Chapter 1 Overview of the Libraries

Portability Routines ............................................................................. 1-2
National Language Support Routines (W*32, W*64) ......................... 1-8
  NLS Date and Time Format (W*32, W*64) ..................................... 1-10
POSIX* Routines ................................................................................. 1-11
QuickWin and Graphics Routines (W*32, W*64) ............................. 1-16
Dialog Routines (W*32, W*64) ......................................................... 1-22
COM and AUTO Routines (W*32, W*64) ........................................... 1-23
Miscellaneous Run-Time Routines ..................................................... 1-25

Chapter 2 Descriptions of the Library Routines

ABORT ................................................................................................... 2-2

About This Manual

This manual describes the Intel® Fortran library routines. The routines and their descriptions apply to all platforms unless otherwise noted. Architectural differences, if any, are also noted.

For details on managing and linking libraries with the Intel Fortran compiler, see Building Applications.

This manual is intended for experienced applications programmers who have a basic understanding of Fortran concepts and the Fortran 95/90 language, and are using Intel Fortran in either a single-platform or multiplatform environment.

Some familiarity with programming concepts and your operating system is helpful. This manual is not a Fortran or programming tutorial.

This manual is organized as follows:

• Chapter 1, “Overview of the Libraries”
• Chapter 2, “Descriptions of the Library Routines”

Product Website and Support

For the latest product information, visit the Intel web site:
http://developer.intel.com/software/products/

At this site, you will find comprehensive product information, including:

• Links to each product, where you will find technical information such as white papers and articles
• Links to user forums
• Links to news and events

To find technical support information, to register your product, or to contact Intel, please visit:

Tutorial information on Fortran 95 and Fortran 90

The following commercially published documents provide reference or tutorial information on Fortran 95 and Fortran 90:

Intel® does not endorse these books or recommend them over other books on the same subjects.

Standard and Specification Documents

The following copyrighted standard and specification documents provide descriptions of many of the features found in Intel® Fortran:

- American National Standard Programming Language FORTRAN, ANSI X3.9-1978
  This Standard is equivalent to: International Standards Organization Programming Language Fortran, ISO/IEC 1539:1991 (E).
- American National Standard Programming Language Fortran 95, ANSI X3J3/96-007
  This Standard is equivalent to: International Standards Organization Programming Language Fortran, ISO/IEC 1539-1:1997 (E).
Associated Intel Documents

The following Intel documents provide additional information about the Intel® Fortran Compiler, Intel® architecture, Intel® processors, or tools:

- Intel® Fortran Language Reference
- Intel® Fortran Libraries Reference
- Intel® Visual Fortran Compiler for Windows® Systems Installing and Getting Started
- Intel® Array Visualizer online help reference
- Intel® Array Viewer online help reference
- Using the Intel® License Manager for FLEXlm®
- Intel® C++ Compiler User's Guide
- VTune™ Performance Analyzer online help
- Enhanced Debugger online help
- Pentium® Processor Family Developer's Manual
- Intel® Processor Identification with the CPUID Instruction, Intel Corporation, doc. number 241618
- Intel® Itanium® Architecture Manuals
- Intel® Itanium® Architecture Software Conventions & Runtime Architecture Guide
- Intel® Itanium® Assembler User's Guide
- Intel® Itanium® Architecture Assembly Language Reference Guide

Most Intel documents can be found at the Intel web site:

http://developer.intel.com/software/products/

Optimization and Vectorization Terminology and Technology

The following documents provide details on basic optimization and vectorization terminology and technology:

Tutorial information on the Intel Fortran Compiler

For additional training on the Intel Fortran Compiler, choose a course in the Intel® Software College - Course Catalog at https://shale.intel.com/SoftwareCollege/CourseCatalog.asp.

For additional technical product information including white papers about Intel compilers, open the page associated with your product at http://developer.intel.com/software/products/.

Conventions

The following table describes the typographic and terminology conventions used in this manual:

<table>
<thead>
<tr>
<th>Typographic Conventions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extensions to Fortran 95</td>
<td>This color indicates extensions to the Fortran 95 Standard. These extensions may or may not be implemented by other compilers that conform to the language standard.</td>
</tr>
<tr>
<td>AUTOMATIC, INTRINSIC, WRITE</td>
<td>Uppercase letters indicate Fortran95/90 statements, data types, directives, and other syntax keywords. Examples of statement keywords are WRITE, INTEGER, DO, and OPEN.</td>
</tr>
<tr>
<td>option, option</td>
<td>This italic type indicates an keyword arguments in syntax, new terms, emphasized text, or a book title. Most new terms are defined in the Glossary of the Language Reference.</td>
</tr>
<tr>
<td>USE IFQWIN</td>
<td>This courier type indicates a code example, a program name, a derived type name, or a pathname.</td>
</tr>
</tbody>
</table>
About This Manual

CTRL

Small capital letters indicate the names of keys and key sequences, such as CTRL+C.

A plus indicates a combination of keys. For example, CTRL+E means to hold down the CTRL key while pressing the E key.

(choice1 | choice2)

Braces and vertical bars indicate a choice of items. You can usually only choose one of the items in the braces.

[optional item]

In syntax, single square brackets indicate items that are optional. In code examples, they are used to show arrays.

s[, s]...

A horizontal ellipsis (three dots in a row) following an item indicates that the item preceding the ellipsis can be repeated. In code examples, a horizontal ellipsis means that not all of the statements are shown.

Adobe Acrobat*

An asterisk at the end of a word or name indicates it is a third-party product trademark.

Terminology Conventions

compiler option

This term refers to Linux® options and Windows® options that can be used on the compiler command line.

cat (1)

This format refers to an online reference page; the section number of the page is shown in parentheses. For example, a reference to cat(1) indicates that you can find the material on the cat command in Section 1 of the reference pages. To read online reference pages, use the man command. Your operating system documentation also includes reference page descriptions.

Intel Fortran

This term refers to the name of the common compiler language supported by the Intel® Visual Fortran Compiler for Windows® and Intel® Fortran Compiler for Linux® products. For more information on these compilers, see http://developer.intel.com/software/products/.

Fortran

This term refers to language information that is common to ANSI FORTRAN 77, ANSI/ISO Fortran 95/90, and Intel Fortran.

Fortran 95/90

This term refers to language information that is common to ANSI/ISO Fortran 95 and ANSI/ISO Fortran 90.

Fortran 95

This term refers to language features of ANSI/ISO Fortran 95.

Fortran 90

This term refers to language features of ANSI/ISO Fortran 90.

Windows systems

This term refers to all supported Microsoft® Windows operating systems. (See also “Platform Labels”.)

Linux systems

This term refers to all supported Linux operating systems. (See also “Platform Labels”.)

integer

This term refers to the INTEGER(KIND=1), INTEGER(KIND=2), INTEGER (INTEGER(KIND=4)), and INTEGER(KIND=8) data types as a group.

Adobe Acrobat®
The following example shows how this manual's typographic conventions are used to indicate the syntax of the CHMOD portability function:

\[
\text{result} = \text{CHMOD} (\text{name}, \text{mode})
\]

This syntax shows that when you use this routine, you must specify the following:

- The keyword CHMOD.
- A left parenthesis.
- The arguments name and mode, where name is the name of a file and mode is the file permission.
- A terminating right parenthesis.

The syntax is shown in teal color, which indicates the the function is a language extension to Fortran 95.

**Platform Labels**

A *platform* is a combination of operating system and central processing unit (CPU) that provides a distinct environment in which to use a product (in this case, a language). This manual contains information for the following language platforms:

<table>
<thead>
<tr>
<th>Language</th>
<th>Platform(^1)</th>
<th>CPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® Fortran</td>
<td>Linux(^\star)</td>
<td>IA-32</td>
</tr>
<tr>
<td></td>
<td>Linux(^\star)</td>
<td>Intel® Itanium(^\circledast)</td>
</tr>
</tbody>
</table>
Information in this manual applies to all supported platforms unless it is otherwise labeled for a specific platform (or platforms), as follows:

L^*X Applies to Linux* on Intel® IA-32 processors and Intel® Itanium® processors, and IA-32 processors with Intel® Extended Memory 64 Technology (Intel® EM64T).

L^*X32 Applies to Linux on Intel IA-32 processors.

L^*X64 Applies to Linux on Intel Itanium processors.

M^*X32 Applies to Apple* Mac OS* X on Intel IA-32 processors.

W^*64 Applies to Microsoft Windows XP operating systems on Intel Itanium processors.

i32 Applies to 32-bit operating systems on Intel IA-32 processors.

i32em Applies to 32-bit operating systems on IA-32-based systems with Intel® Extended Memory 64 Technology (Intel® EM64T).

i64 Applies to 64-bit operating systems on Intel Itanium processors.

For example, the IOFOCUS specifier (for an OPEN statement) is labeled "(W^*32, W^*64)", so this specifier is valid only on Windows operating systems.
Overview of the Libraries

This chapter provides an overview of the various Intel® Fortran library routines:

- “Portability Routines”
- “National Language Support Routines (W*32, W*64)”
- “POSIX* Routines”
- “QuickWin and Graphics Routines (W*32, W*64)”
- “Dialog Routines (W*32, W*64)”
- “COM and AUTO Routines (W*32, W*64)”
- “Miscellaneous Run-Time Routines”

When you include the statement USE module-name in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement. For more information on the USE statement, see the Language Reference.

All the library routines are language extensions to Fortran 95.

In Chapter 2 of this book, all the library routines are listed alphabetically and described in detail.

NOTE. Intrinsic procedures are described in the Language Reference.

See Also

- The USE statement in the Language Reference
- The section on portability routines in Building Applications
Portability Routines

The portability routines help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows® systems.

To use these routines, add the following statement to the program unit containing the routine:

```fortran
USE IFPORT
```

Table 1-1 summarizes portability routines.

<tr>
<td>RANGET</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>RANSET</td>
<td>Sets the seed for the random number generator</td>
</tr>
<tr>
<td>SEED</td>
<td>Changes the starting point of the random number generator.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>SRAND</td>
<td>Seeds the random number generator used with IRAND and RAND.</td>
</tr>
</tbody>
</table>

### Input and Output:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>Checks a file for accessibility according to mode.</td>
</tr>
<tr>
<td>CHMOD</td>
<td>Changes file attributes.</td>
</tr>
<tr>
<td>FGGETC</td>
<td>Reads a character from an external unit.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Flushes the buffer for an external unit to its associated file.</td>
</tr>
</tbody>
</table>
Table 1-1 Summary of Portability Routines

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPUTC</td>
<td>Writes a character to an external unit.</td>
</tr>
<tr>
<td>FSEEK</td>
<td>Repositions a file on an external unit.</td>
</tr>
<tr>
<td>FTELL, FTELLI8</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>GETC</td>
<td>Reads a character from unit 5.</td>
</tr>
<tr>
<td>GETPOS, GETPOSI8</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>PUTC</td>
<td>Writes a character to unit 6.</td>
</tr>
</tbody>
</table>

**Date and Time:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOCK</td>
<td>Returns current time in “hh:mm:ss” format using a 24-hour clock.</td>
</tr>
<tr>
<td>CLOCKX</td>
<td>Returns the processor clock to the nearest microsecond.</td>
</tr>
<tr>
<td>CTIME</td>
<td>Converts a system time to a 24-character ASCII string.</td>
</tr>
<tr>
<td>DATE</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DATE4</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DCLOCK</td>
<td>Returns the elapsed time in seconds since the start of the current process.</td>
</tr>
<tr>
<td>DTIME</td>
<td>Returns CPU time since later of (1) start of program, or (2) most recent call to DTIME.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Returns elapsed CPU time since the start of program execution.</td>
</tr>
<tr>
<td>FDATE</td>
<td>Returns the current date and time as an ASCII string.</td>
</tr>
<tr>
<td>GETDAT</td>
<td>Returns the date.</td>
</tr>
<tr>
<td>GETTIM</td>
<td>Returns the time.</td>
</tr>
<tr>
<td>GMTIME</td>
<td>Returns Greenwich Mean Time as a 9-element integer array.</td>
</tr>
<tr>
<td>IDATE</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>IDATE4</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>ITIME</td>
<td>Returns current time as a 3-element array (hour, minute, second).</td>
</tr>
<tr>
<td>JDATE</td>
<td>Returns current date as an 8-character string with the Julian date.</td>
</tr>
<tr>
<td>JDATE4</td>
<td>Returns current date as a 10-character string with the Julian date.</td>
</tr>
<tr>
<td>LTIME</td>
<td>Returns local time as a 9-element integer array.</td>
</tr>
<tr>
<td>RTC</td>
<td>Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>SECNDS</td>
<td>Returns number of seconds since midnight, less the value of its argument.</td>
</tr>
<tr>
<td>SETDAT</td>
<td>Sets the date.</td>
</tr>
<tr>
<td>SETTIM</td>
<td>Sets the time.</td>
</tr>
</tbody>
</table>
### Table 1-1: Summary of Portability Routines

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME</td>
<td>As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>TIMEF</td>
<td>Returns the number of seconds since the first time this function was called (or zero).</td>
</tr>
</tbody>
</table>

### Error Handling:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETLASTERROR</td>
<td>Returns the last error set.</td>
</tr>
<tr>
<td>GETLASTERRORQQ</td>
<td>Returns the last error set by a run-time function or subroutine.</td>
</tr>
<tr>
<td>IERRNO</td>
<td>Returns the last code error.</td>
</tr>
<tr>
<td>SETERRORMODEQQ</td>
<td>Sets the mode for handling critical errors.</td>
</tr>
</tbody>
</table>

### Program Call and Control:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISEQQ</td>
<td>Sends an interrupt to the executing program, simulating an interrupt from the operating system.</td>
</tr>
<tr>
<td>RUNQQ</td>
<td>Calls another program and waits for it to execute.</td>
</tr>
<tr>
<td>SIGNALQQ</td>
<td>Controls signal handling.</td>
</tr>
<tr>
<td>SLEEPQQ</td>
<td>Delays execution of the program for a specified time.</td>
</tr>
</tbody>
</table>

### System, Drive, or Directory Control and Inquiry:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>CHANGEDIRQQ</td>
<td>Makes the specified directory the current (default) directory.</td>
</tr>
<tr>
<td>CHANGEDRIVEQQ</td>
<td>Makes the specified drive the current drive.</td>
</tr>
<tr>
<td>DELDIRQQ</td>
<td>Deletes a specified directory.</td>
</tr>
<tr>
<td>GETDRIVEDIRQQ</td>
<td>Returns the current drive and directory path.</td>
</tr>
<tr>
<td>GETDRIVESIZEQQ</td>
<td>Returns the size of the specified drive.</td>
</tr>
<tr>
<td>GETDRIVESQQ</td>
<td>Returns the drives available to the system.</td>
</tr>
<tr>
<td>GETENVQQ</td>
<td>Returns a value from the current environment.</td>
</tr>
<tr>
<td>MAKEDIRQQ</td>
<td>Creates a directory with the specified directory name.</td>
</tr>
<tr>
<td>SETENVQQ</td>
<td>Adds a new environment variable or sets the value of an existing one.</td>
</tr>
<tr>
<td>SYSTEMQQ</td>
<td>Executes a command by passing a command string to the operating system's command interpreter.</td>
</tr>
</tbody>
</table>

### Speakers:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>File Management:</strong></td>
<td></td>
</tr>
<tr>
<td>DELFILESQQ</td>
<td>Deletes the specified files in a specified directory.</td>
</tr>
<tr>
<td>FINDFILEQQ</td>
<td>Searches for a file in the directories specified in the PATH environment</td>
</tr>
<tr>
<td></td>
<td>variable.</td>
</tr>
<tr>
<td>FULLPATHQQ</td>
<td>Returns the full path for a specified file or directory.</td>
</tr>
<tr>
<td>GETFILEINFOQQ</td>
<td>Returns information about files with names that match a request string.</td>
</tr>
<tr>
<td>PACKTIMEQQ</td>
<td>Packs time values for use by SETFILETIMEQQ.</td>
</tr>
<tr>
<td>RENAMEFILEQQ</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>SETFILEACCESSQQ</td>
<td>Sets file-access mode for the specified file.</td>
</tr>
<tr>
<td>SETFILETIMEQQ</td>
<td>Sets modification time for the specified file.</td>
</tr>
<tr>
<td>SPLITPATHQQ</td>
<td>Breaks a full path into four components.</td>
</tr>
<tr>
<td>UNPACKTIMEQQ</td>
<td>Unpacks a file's packed time and date value into its component parts.</td>
</tr>
<tr>
<td><strong>Arrays:</strong></td>
<td></td>
</tr>
<tr>
<td>BSEARCHQQ</td>
<td>Performs a binary search for a specified element on a sorted one-dimensional array of intrinsic type.</td>
</tr>
<tr>
<td>SORTQQ</td>
<td>Sorts a one-dimensional array of intrinsic type.</td>
</tr>
<tr>
<td><strong>Floating-Point Inquiry and Control:</strong></td>
<td></td>
</tr>
<tr>
<td>CLEARSTATUSFPQQ</td>
<td>Clears the exception flags in the floating-point processor status word.</td>

# Overview of the Libraries

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPORT_CONNECT_EX</td>
<td>Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.</td>
</tr>
<tr>
<td>SPORT_GET_HANDLE</td>
<td>Returns the Windows® handle associated with the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE</td>
<td>Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE_EX</td>
<td>Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_TIMEOUTS</td>
<td>Returns the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_PEEK_DATA</td>
<td>Returns information about the availability of input data.</td>
</tr>
<tr>
<td>SPORT_PEEK_LINE</td>
<td>Returns information about the availability of input records.</td>
</tr>
<tr>
<td>SPORT_PURGE</td>
<td>Executes a purge function on the specified port.</td>
</tr>
<tr>
<td>SPORT_READ_DATA</td>
<td>Reads available data from the port specified.</td>
</tr>
<tr>
<td>SPORT_READ_LINE</td>
<td>Reads a record from the port specified.</td>
</tr>
<tr>
<td>SPORT_RELEASE</td>
<td>Releases a serial port that has previously been connected.</td>
</tr>
<tr>
<td>SPORT_SET_STATE</td>
<td>Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_STATE_EX</td>
<td>Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_TIMEOUTS</td>
<td>Sets the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_SHOW_STATE</td>
<td>Displays the state of a port.</td>
</tr>
<tr>
<td>SPORT_SPECIAL_FUNC</td>
<td>Executes a communications function on a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_DATA</td>
<td>Outputs data to a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_LINE</td>
<td>Outputs data to a specified port and follows it with a record terminator.</td>
</tr>
<tr>
<td>LNBLNK</td>
<td>Returns the index of the last non-blank character in a string.</td>
</tr>
<tr>
<td>QSORT</td>
<td>Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.</td>
</tr>
<tr>
<td>RINDEX</td>
<td>Returns the index of the last occurrence of a substring in a string.</td>
</tr>
<tr>
<td>SCANENV</td>
<td>Scans the environment for the value of an environment variable.</td>
</tr>
<tr>
<td>TTYNAM</td>
<td>Checks whether a logical unit is a terminal.</td>
</tr>
</tbody>
</table>

1. This routine can also be specified as HOSTNM.
2. There is a RANDOM function and a RANDOM subroutine in the portability library.
3. W*32, W*64
For more information, see the section on portability routines in Building Applications.

**National Language Support Routines (W*32, W*64)**

The National Language Support (NLS) routines provide language localization and a multibyte character set (MBCS) to let you write applications in different languages.

To use an NLS routine, add the following statement to the program unit containing the routine:

```fortran
USE IFNLS
```

Table 1-2 summarizes the NLS routines. Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Locale Setting and Inquiry:</strong></td>
<td></td>
</tr>
<tr>
<td>NLSEnumCodepages</td>
<td>Returns all the supported codepages on the system.</td>
</tr>
<tr>
<td>NLSEnumLocales</td>
<td>Returns all the languages and country combinations supported by the system.</td>
</tr>
<tr>
<td>NLSGetEnvironmentCodepage</td>
<td>Returns the codepage number for the system codepage or the console codepage.</td>
</tr>
<tr>
<td>NLSGetLocale</td>
<td>Returns the current language, country, and codepage.</td>
</tr>
<tr>
<td>NLSGetLocaleInfo</td>
<td>Returns requested information about the current local code set.</td>
</tr>
<tr>
<td>NLSSetEnvironmentCodepage</td>
<td>Changes the codepage for the current console.</td>
</tr>
<tr>
<td>NLSSetLocale</td>
<td>Sets the language, country, and codepage.</td>
</tr>
<tr>
<td><strong>Formatting:</strong></td>
<td></td>
</tr>
<tr>
<td>NLSFormatCurrency</td>
<td>Formats a number string and returns the correct currency string for the</td>
</tr>
<tr>
<td></td>
<td>current locale.</td>
</tr>
<tr>
<td>NLSFormatDate</td>
<td>Returns a correctly formatted string containing the date for the current</td>
</tr>
<tr>
<td></td>
<td>locale.</td>
</tr>
<tr>
<td>NLSFormatNumber</td>
<td>Formats a number string and returns the correct number string for the</td>
</tr>
<tr>
<td></td>
<td>current locale.</td>
</tr>
<tr>
<td>NLSFormatTime</td>
<td>Returns a correctly formatted string containing the time for the current</td>
</tr>
<tr>
<td></td>
<td>locale.</td>
</tr>
<tr>
<td><strong>MBCS Inquiry:</strong></td>
<td></td>
</tr>
<tr>
<td>MBCharLen</td>
<td>Returns the length of the first multibyte character in a string.</td>
</tr>
<tr>
<td>MBCurMax</td>
<td>Returns the longest possible multibyte character for the current codepage.</td>
</tr>
</tbody>
</table>
### Table 1-2 Summary of NLS Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBLead</td>
<td>Determines whether a given character is the first byte of a multibyte character.</td>
</tr>
<tr>
<td>MBLen</td>
<td>Returns the number of multibyte characters in a string, including trailing spaces.</td>
</tr>
<tr>
<td>MBLen_Trim</td>
<td>Returns the number of multibyte characters in a string, not including trailing spaces.</td>
</tr>
<tr>
<td>MBNext</td>
<td>Returns the string position of the first byte of the multibyte character immediately after the given string position.</td>
</tr>
<tr>
<td>MBPrev</td>
<td>Returns the string position of the first byte of the multibyte character immediately before the given string position.</td>
</tr>
<tr>
<td>MBStrLead</td>
<td>Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.</td>
</tr>
</tbody>
</table>

#### MBCS Conversion:

- **MBConvertMBCToUnicode**: Converts a character string from a multibyte codepage to a Unicode string.
- **MBConvertUnicodeToMB**: Converts a Unicode string to a multibyte character string of the current codepage.
- **MBJISTToJMS**: Converts a Japan Industry Standard (JIS) character to a Microsoft Kanji (Shift JIS or JMS) character.
- **MBJMSTToJIS**: Converts a Microsoft Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.

#### MBCS Fortran Equivalent:

- **MBINCHARQQ**: Same as INCHARQQ except that it can read a single multibyte character at once and returns the number of bytes read.
- **MBINDEX**: Same as INDEX except that multibyte characters can be included in its arguments.
- **MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE**: Same as LGE, LGT, LLE, LLT, and the operators .EQ. and .NE. except that multibyte characters can be included in their arguments.
- **MBSCAN**: Same as SCAN except that multibyte characters can be included in its arguments.
- **MBVERIFY**: Same as VERIFY except that multibyte characters can be included in its arguments.

For more information, see the section on National Language Support routines in *Building Applications.*
NLS Date and Time Format (W*32, W*64)

When NLSGetLocaleInfo (type, outstr) returns information about the date and time formats of the current locale, the value returned in outstr can be interpreted according to the following tables. Any text returned within a date and time string that is enclosed within single quotes should be left in the string in its exact form; that is, do not change the text or the location within the string.

Day

The day can be displayed in one of four formats using the letter "d". The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Day of the month as digits without leading zeros for single-digit days</td>
</tr>
<tr>
<td>dd</td>
<td>Day of the month as digits with leading zeros for single-digit days</td>
</tr>
<tr>
<td>ddd</td>
<td>Day of the week as a three-letter abbreviation (SABBREVDAYNAME)</td>
</tr>
<tr>
<td>dddd</td>
<td>Day of the week as its full name (SDAYNAME)</td>
</tr>
</tbody>
</table>

Month

The month can be displayed in one of four formats using the letter "M". The uppercase “M” distinguishes months from minutes. The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Month as digits without leading zeros for single-digit months</td>
</tr>
<tr>
<td>MM</td>
<td>Month as digits with leading zeros for single-digit months</td>
</tr>
<tr>
<td>MMM</td>
<td>Month as a three-letter abbreviation (SABBREVMONTHNAME)</td>
</tr>
<tr>
<td>MMMM</td>
<td>Month as its full name (SMONTHNAME)</td>
</tr>
</tbody>
</table>

Year

The year can be displayed in one of three formats using the letter "y". The following table shows the three variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>Year represented by only the last digit</td>
</tr>
<tr>
<td>yy</td>
<td>Year represented by only the last two digits</td>
</tr>
<tr>
<td>yyyy</td>
<td>Year represented by the full 4 digits</td>
</tr>
</tbody>
</table>

Period/Era

The period/era string is displayed in a single format using the letters "gg".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gg</td>
<td>Period/Era string</td>
</tr>
</tbody>
</table>
Time
The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker. The following table shows the numerous variations of the time format. Lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The lowercase "m" distinguishes minutes from months.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>Hours without leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>hh</td>
<td>Hours with leading zeros for single-digit hours (12 hour clock)</td>
</tr>
<tr>
<td>H</td>
<td>Hours without leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>HH</td>
<td>Hours with leading zeros for single-digit hours (24 hour clock)</td>
</tr>
<tr>
<td>m</td>
<td>Minutes without leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>mm</td>
<td>Minutes with leading zeros for single-digit minutes</td>
</tr>
<tr>
<td>s</td>
<td>Seconds without leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>ss</td>
<td>Seconds with leading zeros for single-digit seconds</td>
</tr>
<tr>
<td>t</td>
<td>One-character time marker string</td>
</tr>
<tr>
<td>tt</td>
<td>Multicharacter time marker string</td>
</tr>
</tbody>
</table>

See Also: “NLSGetLocaleInfo”

Example
USE IFNLS
INTEGER(4) strlen
CHARACTER(40) str
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str ! prints Monday if language is English
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str ! prints Tuesday if language is English

POSIX* Routines
The POSIX routines help you write Fortran programs that comply with the POSIX Standard. They implement the IEEE POSIX FORTRAN-77 language bindings.
To use a POSIX routine, add the following statement to the program unit containing the routine:
USE IFPOSIX
Table 1-3 summarizes the Intel Fortran POSIX library routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPXFARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>IPXFCONST</td>
<td>Returns the value associated with a constant defined in the C POSIX standard.</td>
</tr>
<tr>
<td>IPXFLENTTRIM</td>
<td>Returns the index of the last non-blank character in an input string.</td>
</tr>
<tr>
<td>IPXFWEXITSTATUS 1</td>
<td>Returns the exit code of a child process.</td>
</tr>
<tr>
<td>IPXFWSTOPSIG 1</td>
<td>Returns the number of the signal that caused a child process to stop.</td>
</tr>
<tr>
<td>IPXFWTERMSIG 1</td>
<td>Returns the number of the signal that caused a child process to terminate.</td>
</tr>
<tr>
<td>PXF&lt;TYPE&gt;GET</td>
<td>Gets the value stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXF&lt;TYPE&gt;SET</td>
<td>Sets the value of a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA&lt;TYPE&gt;GET</td>
<td>Gets the array values stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA&lt;TYPE&gt;SET</td>
<td>Sets the value of an array component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFACCESS</td>
<td>Determines the accessibility of a file.</td>
</tr>
<tr>
<td>PXFALARM</td>
<td>Schedules an alarm.</td>
</tr>
<tr>
<td>PXFCALLSUBHANDLE</td>
<td>Calls the associated subroutine.</td>
</tr>
<tr>
<td>PXFCFGETISPEED 1</td>
<td>Returns the input baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFGETOSPEED 1</td>
<td>Returns the output baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETISPEED 1</td>
<td>Sets the input baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETOSPEED 1</td>
<td>Sets the output baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>PXFCHMOD</td>
<td>Changes the ownership mode of the file.</td>
</tr>
<tr>
<td>PXFCHOWN 1</td>
<td>Changes the owner and group of a file.</td>
</tr>
<tr>
<td>PXFCLEARENV</td>
<td>Clears the process environment.</td>
</tr>
<tr>
<td>PXFCLOSE</td>
<td>Closes the file associated with the descriptor.</td>
</tr>
<tr>
<td>PXFCLOSEDIR</td>
<td>Closes the directory stream.</td>
</tr>
<tr>
<td>PXFCONST</td>
<td>Returns the value associated with a constant.</td>
</tr>
<tr>
<td>PXFCNTL 1</td>
<td>Manipulates an open file descriptor.</td>
</tr>
<tr>
<td>PXFCREAT</td>
<td>Creates a new file or rewrites an existing file.</td>
</tr>
<tr>
<td>PXFCTERMID 1</td>
<td>Generates a terminal pathname.</td>
</tr>
<tr>
<td>PXFDUP, PXFDUP2</td>
<td>Duplicates an existing file descriptor.</td>
</tr>
<tr>
<td>PXFE&lt;TYPE&gt;GET</td>
<td>Gets the value stored in an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFE&lt;TYPE&gt;SET</td>
<td>Sets the value of an array element component (or field) of a structure.</td>
</tr>
</tbody>
</table>
### Table 1-3 Summary of POSIX Routines

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PXFEXECV, PXFEXECVE, PXFEXECVP</td>
<td>Execute a new process by passing command-line arguments.</td>
</tr>
<tr>
<td>PXFEXIT, PXFFASTEXIT</td>
<td>Exits from a process.</td>
</tr>
<tr>
<td>PXFFDOPEN</td>
<td>Opens an external unit.</td>
</tr>
<tr>
<td>PXFFFLUSH</td>
<td>Flushes a file directly to disk.</td>
</tr>
<tr>
<td>PXFFGETC</td>
<td>Reads a character from a file.</td>
</tr>
<tr>
<td>PXFFILENO</td>
<td>Returns the file descriptor associated with a specified unit.</td>
</tr>
<tr>
<td>PXFFORK¹</td>
<td>Creates a child process that differs from the parent process only in its PID.</td>
</tr>
<tr>
<td>PXFPPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFFPUTC</td>
<td>Writes a character to a file.</td>
</tr>
<tr>
<td>PXFFSEEK</td>
<td>Modifies a file position.</td>
</tr>
<tr>
<td>PXFFSTAT</td>
<td>Gets a file’s status information.</td>
</tr>
<tr>
<td>PXFFTELL</td>
<td>Returns the relative position in bytes from the beginning of the file.</td>
</tr>
<tr>
<td>PXFGETARG</td>
<td>Tests whether a file descriptor is connected to a terminal.</td>
</tr>
<tr>
<td>PXFGETC</td>
<td>Reads a character from standard input unit 5.</td>
</tr>
<tr>
<td>PXFGETCWD</td>
<td>Returns the path of the current working directory.</td>
</tr>
<tr>
<td>PXFGETEGID¹</td>
<td>Gets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETENV</td>
<td>Gets the setting of an environment variable.</td>
</tr>
<tr>
<td>PXFGETEUID¹</td>
<td>Gets the effective user ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGID¹</td>
<td>Gets the real group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGRGID¹</td>
<td>Gets group information for the specified GID.</td>
</tr>
<tr>
<td>PXFGETGRNAM¹</td>
<td>Gets group information for the named group.</td>
</tr>
<tr>
<td>PXFGETGROUPS¹</td>
<td>Gets supplementary group IDs.</td>
</tr>
<tr>
<td>PXFGETLOGIN</td>
<td>Gets the name of the user.</td>
</tr>
<tr>
<td>PXFGETPGRP¹</td>
<td>Gets the process group ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPID</td>
<td>Gets the process ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPPID</td>
<td>Gets the process ID of the parent of the calling process.</td>
</tr>
<tr>
<td>PXFGETPWNAM¹</td>
<td>Gets password information for a specified name.</td>
</tr>
<tr>
<td>PXFGETPWUID¹</td>
<td>Gets password information for a specified UID.</td>
</tr>
</tbody>
</table>
### Table 1-3 Summary of POSIX Routines

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>PXFGETSUBHANDLE</td>
<td>Returns a handle for a subroutine.</td>
</tr>
<tr>
<td>PXFGETUID(^1)</td>
<td>Gets the real user ID of the current process.</td>
</tr>
<tr>
<td>PXFISBLK</td>
<td>Tests for a block special file.</td>
</tr>
<tr>
<td>PXFISCHR</td>
<td>Tests for a character file.</td>
</tr>
<tr>
<td>PXFISCONST</td>
<td>Tests whether a string is a valid constant name.</td>
</tr>
<tr>
<td>PXFISDIR</td>
<td>Tests whether a file is a directory.</td>
</tr>
<tr>
<td>PXFISFIFO</td>
<td>Tests whether a file is a special FIFO file.</td>
</tr>
<tr>
<td>PXFISREG</td>
<td>Tests whether a file is a regular file.</td>
</tr>
<tr>
<td>PXFKILL</td>
<td>Sends a signal to a specified process.</td>
</tr>
<tr>
<td>PXFLINK</td>
<td>Creates a link to a file or directory.</td>
</tr>
<tr>
<td>PXFLOCALTIME</td>
<td>Converts a given elapsed time in seconds to local time.</td>
</tr>
<tr>
<td>PXFSEEK</td>
<td>Positions a file a specified distance in bytes.</td>
</tr>
<tr>
<td>PXFMKDIR</td>
<td>Creates a new directory.</td>
</tr>
<tr>
<td>PXFMKFIFO(^1)</td>
<td>Creates a new FIFO.</td>
</tr>
<tr>
<td>PXFOPEN</td>
<td>Opens or creates a file.</td>
</tr>
<tr>
<td>PXFOPENDIR</td>
<td>Opens a directory and associates a stream with it.</td>
</tr>
<tr>
<td>PXFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFPAUSE</td>
<td>Suspends process execution.</td>
</tr>
<tr>
<td>PXFPIPE</td>
<td>Creates a communications pipe between two processes.</td>
</tr>
<tr>
<td>PXFPOSIXIO</td>
<td>Sets the current value of the POSIX I/O flag.</td>
</tr>
<tr>
<td>PXFPUTC</td>
<td>Outputs a character to logical unit 6 (stdout).</td>
</tr>
<tr>
<td>PXFREAD</td>
<td>Reads from a file.</td>
</tr>
<tr>
<td>PXFREADDIR</td>
<td>Reads the current directory entry.</td>
</tr>
<tr>
<td>PXFRENAME</td>
<td>Changes the name of a file.</td>
</tr>
<tr>
<td>PXFREWINDDIR</td>
<td>Resets the position of the stream to the beginning of the directory.</td>
</tr>
<tr>
<td>PXFRMDIR</td>
<td>Removes a directory.</td>
</tr>
<tr>
<td>PXFSETENV</td>
<td>Adds a new environment variable or sets the value of an environment variable.</td>
</tr>
<tr>
<td>PXFSETGID(^1)</td>
<td>Sets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFSETPGID(^1)</td>
<td>Sets the process group ID.</td>
</tr>
<tr>
<td>PXFSETSID(^1)</td>
<td>Creates a session and sets the process group ID.</td>
</tr>
<tr>
<td>PXFSETUID(^1)</td>
<td>Sets the effective user ID of the current process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFSIGACTION</td>
<td>Changes the action associated with a specific signal.</td>
</tr>
<tr>
<td>PXFSIGADDSET¹</td>
<td>Adds a signal to a signal set.</td>
</tr>
<tr>
<td>PXFSIGDELSET¹</td>
<td>Deletes a signal from a signal set.</td>
</tr>
<tr>
<td>PXFSIGEMPTYSET¹</td>
<td>Empties a signal set.</td>
</tr>
<tr>
<td>PXFSIGFILLSET¹</td>
<td>Fills a signal set.</td>
</tr>
<tr>
<td>PXFSIGISMEMBER¹</td>
<td>Tests whether a signal is a member of a signal set.</td>
</tr>
<tr>
<td>PXFSIGPENDING¹</td>
<td>Examines pending signals.</td>
</tr>
<tr>
<td>PXFSIGPROCMASK¹</td>
<td>Changes the list of currently blocked signals.</td>
</tr>
<tr>
<td>PXFSIGSUSPEND¹</td>
<td>Suspends the process until a signal is received.</td>
</tr>
<tr>
<td>PXFSLEEP</td>
<td>Forces the process to sleep.</td>
</tr>
<tr>
<td>PXFSTAT</td>
<td>Gets the status of a file.</td>
</tr>
<tr>
<td>PXFSTRUCTCOPY</td>
<td>Copies the contents of one structure to another.</td>
</tr>
<tr>
<td>PXFSTRUCTCREATE</td>
<td>Creates an instance of the specified structure.</td>
</tr>
<tr>
<td>PXFSTRUCTFREE</td>
<td>Deletes the instance of a structure.</td>
</tr>
<tr>
<td>PXFSYSCONF</td>
<td>Gets values for system limits or options.</td>
</tr>
<tr>
<td>PXFTCDRAIN¹</td>
<td>Waits until all output written has been transmitted.</td>
</tr>
<tr>
<td>PXFTCFLOW¹</td>
<td>Suspends the transmission or reception of data.</td>
</tr>
<tr>
<td>PXFTCFLUSH¹</td>
<td>Discards terminal input data, output data, or both.</td>
</tr>
<tr>
<td>PXFTCGETATTR¹</td>
<td>Reads current terminal settings.</td>
</tr>
<tr>
<td>PXFTCGETPGRP¹</td>
<td>Gets the foreground process group ID associated with the terminal.</td>
</tr>
<tr>
<td>PXFTCSENDBREAK¹</td>
<td>Sends a break to the terminal.</td>
</tr>
<tr>
<td>PXFTCSETATTR¹</td>
<td>Writes new terminal settings.</td>
</tr>
<tr>
<td>PXFTCSETPGRP¹</td>
<td>Sets the foreground process group associated with the terminal.</td>
</tr>
<tr>
<td>PXFTIME</td>
<td>Gets the system time.</td>
</tr>
<tr>
<td>PXFTIMES</td>
<td>Gets process times.</td>
</tr>
<tr>
<td>PXFTTYNAM¹</td>
<td>Gets the terminal pathname.</td>
</tr>
<tr>
<td>PXFUCOMPARE</td>
<td>Compares two unsigned integers.</td>
</tr>
<tr>
<td>PXFU MASK</td>
<td>Sets a new file creation mask and gets the previous one.</td>
</tr>
<tr>
<td>PXFUNAME</td>
<td>Gets the operation system name.</td>
</tr>
<tr>
<td>PXFUNLINK</td>
<td>Removes a directory entry.</td>
</tr>
<tr>
<td>PXFUTIME</td>
<td>Sets file access and modification times.</td>
</tr>
</tbody>
</table>
QuickWin and Graphics Routines (W*32, W*64)

QuickWin routines help you turn graphics programs into simple Windows* applications.

The graphics routines can be used in Standard Graphics applications and in Quickwin applications. They can also be used in QuickWin applications.

To use a Quickwin or graphics routine, add the following statement to the program unit containing the routine:

USE IFQWIN

For graphics routines, you must also choose the QuickWin Graphics or Standard Graphics program type.

Table 1-4 summarizes the QuickWin routines.

### Table 1-4 Summary of QuickWin Routines (W*32, W*64)

**QuickWin Application Enhancement:**

- ABOUTBOXQQ: Adds an About Box with customized text.
- APPENDMENUQQ: Appends a menu item.
- CLICKMENUQQ: Simulates the effect of clicking or selecting a menu item.
- DELETEMENUQQ: Deletes a menu item.
- GETEXITQQ: Returns the setting for a QuickWin application's exit behavior.
- INCHARQQ: Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering.
- INITIALSETTINGS: Controls initial menu settings and initial frame window.
- INSERTMENUQQ: Inserts a menu item.
- MESSAGEBOXQQ: Displays a message box.
- MODIFYMENUFLAGSQQ: Modifies a menu item's state.
- MODIFYMENUROUTINEQQ: Modifies a menu item's callback routine.
- MODIFYMENUSTRINGQQ: Modifies a menu item's text string.
- PASSDIRKEYSQQ: Determines the behavior of direction and page keys.
- REGISTERMOUSEEVENT: Registers the application defined routines to be called on mouse events.
- SETEXITQQ: Sets a QuickWin application's exit behavior.
- SETMESSAGEQQ: Changes any QuickWin message, including status bar messages, state messages, and dialog box messages.
- SETMOUSECURSOR: Sets the mouse cursor for the window in focus.
- SETWINDOWMENUQQ: Sets the menu to which a list of current child window names are appended.
- UNREGISTERMOUSEEVENT: Removes the routine registered by REGISTERMOUSEEVENT.
- WAITONMOUSEEVENT: Blocks a return until a mouse event occurs.

**Color Conversion:**

- INTEGERTORGB: Converts an RGB color value to its red, green, and blue components.
- RGBTOINTEGER: Converts integers specifying red, green, and blue color into an RGB integer (for use in RGB routines).

For more information, see the section on using QuickWin in *Building Applications*. 
Table 1-5 summarizes the graphics routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Color Control or Inquiry: 1</td>
<td></td>
</tr>
<tr>
<td>FLOODFILL</td>
<td>Fills an area using the current index and fill mask; fill starting point uses viewport coordinates.</td>
</tr>
<tr>
<td>FLOODFILL_W</td>
<td>Fills an area using the current index and fill mask; fill starting point uses window coordinates.</td>
</tr>
<tr>
<td>FLOODFILLRGB</td>
<td>Fills an area using the current RGB color and fill mask; fill starting point uses viewport coordinates.</td>
</tr>
<tr>
<td>FLOODFILLRGB_W</td>
<td>Fills an area using the current RGB color and fill mask; fill starting point uses viewport coordinates.</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>Returns current background color index for both text and graphics.</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>Returns current background RGB color value for both text and graphics.</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>Returns the current graphics color index.</td>

<tr>
<td>GETVIEWCOORD</td>
<td>Converts physical coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETVIEWCOORD_W</td>
<td>Converts window coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETWINDOWCOORD</td>
<td>Converts viewport coordinates to window coordinates.</td>
</tr>
<tr>
<td>SETVIEWORG</td>
<td>Moves the viewport coordinate origin (0,0) to a specified physical point.</td>
</tr>
<tr>
<td>SETVIEWPORT</td>
<td>Redefines viewport bounds to the specified limits and sets the viewport</td>
</tr>
<tr>
<td></td>
<td>coordinate origin to the upper-left corner of this region.</td>
</tr>
<tr>
<td>SETWINDOW</td>
<td>Defines a window bound by specified window coordinates.</td>
</tr>
</tbody>
</table>

### Graphics Drawing:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC</td>
<td>Draws an arc using viewport coordinates.</td>
</tr>
<tr>
<td>ARC_W</td>
<td>Draws an arc using window coordinates.</td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>Clears the screen, viewport, or text window.</td>
</tr>
</tbody>
</table>
### Table 1-5  Summary of Graphics Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELLIPSE</td>
<td>Draws an ellipse or circle using viewport coordinates.</td>
</tr>
<tr>
<td>ELLIPSE_W</td>
<td>Draws an ellipse or circle using window coordinates.</td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>Returns the endpoints of the most recently drawn arc or pie.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION</td>
<td>Returns the viewport coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION_W</td>
<td>Returns the window coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GRSTATUS</td>
<td>Returns the status (success or failure) of the most recently called graphics routine.</td>
</tr>
<tr>
<td>LINETO</td>
<td>Draws a line from the current graphics-output position to a specified point using viewport coordinates.</td>
</tr>
<tr>
<td>LINETO_W</td>
<td>Draws a line from the current graphics-output position to a specified point using window coordinates.</td>
</tr>
<tr>
<td>LINETOAR</td>
<td>Draws a line between points in one array and corresponding points in another array.</td>
</tr>
<tr>
<td>LINETOAREX</td>
<td>Similar to LINETOAR, but also lets you specify color and line style.</td>
</tr>
<tr>
<td>MOVETO</td>
<td>Moves the current graphics-output position to a specified point using viewport coordinates.</td>
</tr>
<tr>
<td>MOVETO_W</td>
<td>Moves the current graphics-output position to a specified point using window coordinates.</td>
</tr>
<tr>
<td>PIE</td>
<td>Draws a pie-slice-shaped figure using viewport coordinates.</td>
</tr>
<tr>
<td>PIE_W</td>
<td>Draws a pie-slice-shaped figure using window coordinates.</td>
</tr>
<tr>
<td>POLYBEZIER</td>
<td>Draws a Bezier curve using viewport coordinates.</td>
</tr>
<tr>
<td>POLYBEZIER_W</td>
<td>Draws a Bezier curve using window coordinates.</td>
</tr>
<tr>
<td>POLYBEZIERTO</td>
<td>Draws a Bezier curve using viewport coordinates.</td>
</tr>
<tr>
<td>POLYBEZIERTO_W</td>
<td>Draws a Bezier curve using window coordinates.</td>
</tr>
<tr>
<td>POLYGON</td>
<td>Draws a polygon using viewport coordinates.</td>
</tr>
<tr>
<td>POLYGON_W</td>
<td>Draws a polygon using window coordinates.</td>
</tr>
<tr>
<td>POLYLINEQ</td>
<td>Draws a line between successive points in an array.</td>
</tr>
<tr>
<td>RECTANGLE</td>
<td>Draws a rectangle using viewport coordinates.</td>
</tr>
<tr>
<td>RECTANGLE_W</td>
<td>Draws a rectangle using window coordinates.</td>
</tr>
</tbody>
</table>

### Character-Based Text Display:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISPLAYCURSOR</td>
<td>Sets the cursor on or off.</td>
</tr>
<tr>
<td>GETTEXTPOSITION</td>
<td>Returns the current text-output position.</td>
</tr>
</tbody>
</table>
### Table 1-5 Summary of Graphics Routines (W'32, W'64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETTEXTWINDOW</td>
<td>Returns the boundaries of the current text window.</td>
</tr>
<tr>
<td>OUTTEXT</td>
<td>Sends text to the screen at the current position.</td>
</tr>
<tr>
<td>SCROLLTEXTWINDOW</td>
<td>Scrolls the contents of a text window.</td>
</tr>
<tr>
<td>SETTEXTCURSOR</td>
<td>Sets the height and width of the text cursor for the window in focus.</td>
</tr>
<tr>
<td>SETTEXTPOSITION</td>
<td>Sets the current text-output position.</td>
</tr>
<tr>
<td>SETTEXTWINDOW</td>
<td>Sets the boundaries of the current text window.</td>
</tr>
<tr>
<td>WRAPON</td>
<td>Turns line wrapping on or off.</td>
</tr>
</tbody>
</table>

**Font-Based Character Display:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETFONTINFO</td>
<td>Returns the current font characteristics.</td>
</tr>
<tr>
<td>GETGTEXTTEXTENT</td>
<td>Returns the width of specified text in the current font.</td>
</tr>
<tr>
<td>GETGTEXTROTATION</td>
<td>Returns the current orientation of the font text output by OUTGTEXT.</td>
</tr>
<tr>
<td>INITIALIZEFONTS</td>
<td>Initializes the font library.</td>
</tr>
</tbody>
</table>
| OUTGTEXT              | Sends text in the current font to the screen at the current position.  
| SETFONT               | Finds one font that matches a specified set of characteristics and makes it the current font used by OUTGTEXT. |
| SETGTEXTROTATION      | Sets the orientation angle of font text output in degrees.                                                                                     |

**Image Transfers in Memory:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETIMAGE</td>
<td>Stores a screen image using viewport coordinates.</td>
</tr>
<tr>
<td>GETIMAGE_W</td>
<td>Stores a screen image using window coordinates.</td>
</tr>
<tr>
<td>IMAGESIZE</td>
<td>Returns a viewport-coordinate image size in bytes.</td>
</tr>
<tr>
<td>IMAGESIZE_W</td>
<td>Returns a window-coordinate image size in bytes.</td>
</tr>
<tr>
<td>PUTIMAGE</td>
<td>Retrieves a viewport-coordinate image from memory and displays it.</td>
</tr>
<tr>
<td>PUTIMAGE_W</td>
<td>Retrieves a window-coordinate image from memory and displays it.</td>
</tr>
</tbody>
</table>

**Image Loading and Saving:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOADIMAGE</td>
<td>Reads a Windows bitmap file (.BMP) from disk and displays it as specified viewport coordinates.</td>
</tr>
<tr>
<td>LOADIMAGE_W</td>
<td>Reads a Windows bitmap file (.BMP) from disk and displays it as specified window coordinates.</td>
</tr>
<tr>
<td>SAVEIMAGE</td>
<td>Saves an image from a specified part of the screen and saves it as a Windows bitmap file; screen location is specified using viewport coordinates.</td>
</tr>
</tbody>
</table>
Table 1-5 Summary of Graphics Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAVEIMAGE_W</td>
<td>Saves an image from a specified part of the screen and saves it as a Windows bitmap file; screen location is specified using window coordinates.</td>
</tr>
</tbody>
</table>

For more information, see the sections on using QuickWin and drawing graphics in *Building Applications*.

**Dialog Routines (W*32, W*64)**

The dialog routines let you add dialog boxes to Windows*, QuickWin, and console applications. To activate a dialog box, add the following statement to the application’s relevant program unit:

```
USE IFLOGM
```

Table 1-6 summarizes the dialog routines.

Table 1-6 Summary of Dialog Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLGEXIT</td>
<td>Closes an open dialog box.</td>
</tr>
<tr>
<td>DLGFLUSH</td>
<td>Updates the display of a dialog box.</td>
</tr>
<tr>
<td>DLGGET</td>
<td>Returns the value of a control variable.</td>
</tr>
<tr>
<td>DLGGETCHAR</td>
<td>Returns the value of a character control variable.</td>
</tr>
<tr>
<td>DLGGETINT</td>
<td>Returns the value of an integer control variable.</td>
</tr>
<tr>
<td>DLGGETLOG</td>
<td>Returns the value of a logical control variable.</td>
</tr>
<tr>
<td>DLGINIT</td>
<td>Initializes a dialog box.</td>
</tr>
<tr>
<td>DLGINITWITHRESOURCEHANDLE</td>
<td>Initializes a dialog box.</td>
</tr>
<tr>
<td>DLGISDLGMESSAGE</td>
<td>Determines whether a message is intended for a modeless dialog box.</td>
</tr>
<tr>
<td>DLGISDLGMESSAGEWITHDLG</td>
<td>Determines whether a message is intended for a specific modeless dialog box.</td>
</tr>
<tr>
<td>DLGMODAL</td>
<td>Displays a dialog box.</td>
</tr>
<tr>
<td>DLGMODALWITHPARENT</td>
<td>Displays a dialog box and indicates the parent window.</td>
</tr>
<tr>
<td>DLGMODELESS</td>
<td>Displays a modeless dialog box.</td>
</tr>
<tr>
<td>DLGSENDCTRLMESSAGE</td>
<td>Sends a message to a dialog box control.</td>
</tr>
</tbody>
</table>

1. RGB is Red-Green-Blue
2. OUTGTEXT allows use of special fonts; OUTTEXT does not
For more information, see the section on using dialogs in *Building Applications*.

**COM and AUTO Routines (W*32, W*64)**

The COM and Auto routines help you write programs that use Component Object Model (COM) and Automation servers.

To use a COM routine, add the following statement to the program unit containing the routine:

```
USE IFCOM
```

To use an AUTO routine, add the following statement to the program unit containing the routine:

```
USE IFAUTO
```

Some of the routines may also require the statement USE IFWINTY.

**Table 1-7** summarizes the COM routines. Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

**Table 1-7** Summary of COM Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMAddObjectReference</td>
<td>Adds a reference to an object's interface.</td>
</tr>
<tr>
<td>COMCLSIDFromProgID</td>
<td>Passes a programmatic identifier and returns the corresponding class identifier.</td>
</tr>
<tr>
<td>COMCLSIDFromString</td>
<td>Passes a class identifier string and returns the corresponding class identifier.</td>
</tr>
</tbody>
</table>
Table 1-7 Summary of COM Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMCreateObjectByGUID</td>
<td>Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.</td>
</tr>
<tr>
<td>COMCreateObjectByProgID</td>
<td>Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object's IDispatch interface.</td>
</tr>
<tr>
<td>COMGetActiveObjectByGUID</td>
<td>Passes a class identifier and returns a pointer to the interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetActiveObjectByProgID</td>
<td>Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.</td>
</tr>
<tr>
<td>COMGetFileObject</td>
<td>Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file.</td>
</tr>
<tr>
<td>COMInitialize</td>
<td>Initializes the COM library.</td>
</tr>
<tr>
<td>COMIsEqualGUID</td>
<td>Determines whether two globally unique identifiers (GUIDs) are the same.</td>
</tr>
<tr>
<td>COMQueryInterface</td>
<td>Passes an interface identifier and returns a pointer to an object's interface.</td>
</tr>
<tr>
<td>COMReleaseObject</td>
<td>Indicates that the program is done with a reference to an object's interface.</td>
</tr>
<tr>
<td>COMStringFromGUID</td>
<td>Passes a globally unique identifier (GUID) and returns a string of printable characters.</td>
</tr>
<tr>
<td>COMUninitialize</td>
<td>Uninitializes the COM library.</td>
</tr>
</tbody>
</table>

Table 1-8 summarizes the AUTO routines. Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

Table 1-8 Summary of AUTO Routines (W*32, W*64)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOAddArg</td>
<td>Passes an argument name and value and adds the argument to the argument list data structure.</td>
</tr>
<tr>
<td>AUTOAllocateInvokeArgs</td>
<td>Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.</td>
</tr>
<tr>
<td>AUTODeallocateInvokeArgs</td>
<td>Deallocates an argument list data structure.</td>
</tr>
<tr>
<td>AUTOGetExceptInfo</td>
<td>Retrieves the exception information when a method has returned an exception status.</td>
</tr>
<tr>
<td>AUTOGetProperty</td>
<td>Passes the name or identifier of the property and gets the value of the automation object's property.</td>
</tr>
</tbody>
</table>
Overview of the Libraries

Miscellaneous Run-Time Routines

These routines help you write programs for applications. To use for_rtl_init_ and for_rtl_finish_, you must call them from a main program written in C. To use the other routines, add the following statement to the program unit containing the routine:

USE IFCORE

Table 1-9 summarizes these run-time routines:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOGetPropertyByID</td>
<td>Passes the member ID of the property and gets the value of the automation object's property into the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOGetPropertyInvokeArgs</td>
<td>Passes an argument list data structure and gets the value of the automation object's property specified in the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOInvoke</td>
<td>Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments.</td>
</tr>
<tr>
<td>AUTOSetProperty</td>
<td>Passes the name or identifier of the property and a value, and sets the value of the automation object's property.</td>
</tr>
<tr>
<td>AUTOSetPropertyByID</td>
<td>Passes the member ID of the property and sets the value of the automation object's property, using the argument list's first argument.</td>
</tr>
<tr>
<td>AUTOSetPropertyInvokeArgs</td>
<td>Passes an argument list data structure and sets the value of the automation object's property specified in the argument list's first argument.</td>
</tr>
</tbody>
</table>

### Keyboards and Speakers:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETCHARQQ</td>
<td>Returns the next keyboard keystroke.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
</tbody>
</table>

### File Management:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMITQQ</td>
<td>Executes any pending write operations for the file associated with the specified unit to the file's physical device.</td>
</tr>
</tbody>
</table>
Table 1-9 Summary of Miscellaneous Run-Time Routines

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Error Handling:</strong></td>
<td></td>
</tr>
<tr>
<td>GERROR</td>
<td>Returns the IERRNO error code as a string variable.</td>
</tr>
<tr>
<td>PERROR</td>
<td>Returns an error message, preceded by a string, for the last error detected.</td>
</tr>
<tr>
<td><strong>Run-Time Environment:</strong></td>
<td></td>
</tr>
<tr>
<td>for_rtl_finish_</td>
<td>Cleans up the Fortran run-time environment.</td>
</tr>
<tr>
<td>for_rtl_init_</td>
<td>Initializes the Fortran run-time environment.</td>
</tr>
<tr>
<td><strong>Floating-Point Inquiry and Control:</strong></td>
<td></td>
</tr>
<tr>
<td>FOR_GET_FPE</td>
<td>Returns the current settings of floating-point exception flags.</td>
</tr>
<tr>
<td>FOR_SET_FPE</td>
<td>Sets the floating-point exception flags.</td>
</tr>
<tr>
<td>GETEXCEPTIONPTRSQQ1</td>
<td>Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.</td>
</tr>
<tr>
<td><strong>Reentrancy Mode Control:</strong></td>
<td></td>
</tr>
<tr>
<td>FOR_SET_REENTRANCY</td>
<td>Controls the type of reentrancy protection that the Run-Time Library exhibits.</td>
</tr>
<tr>
<td><strong>Traceback:</strong></td>
<td></td>
</tr>
<tr>
<td>TRACEBACKQQ</td>
<td>Generates a stack trace.</td>
</tr>
<tr>
<td><strong>Memory assignment:</strong></td>
<td></td>
</tr>
<tr>
<td>FOR_DESCRIPTOR_ASSIGN1</td>
<td>Creates an array descriptor in memory.</td>
</tr>
</tbody>
</table>

1. W*32, W*64

For more information on traceback, see the section on using traceback information in *Building Applications*. 

1-26
This chapter contains the descriptions of Intel® Fortran library routines listed in alphabetical order. They are all language extensions to Fortran 95.

Modules must be included in programs that contain the following routines:

- **Portability routines**
  These routines require a USE IFPORT statement to access the portability library.

- **POSIX* routines**
  These routines require a USE IFPOSIX statement to access the POSIX library.

- **NLS routines**
  These routines require a USE IFNLS statement to access the NLS library. These routines are only available on Windows* systems.

- **QuickWin and graphics routines**
  These routines require a USE IFQWIN statement to access the Visual Fortran library and graphics modules. These routines are only available on Windows* systems.

- **Serial port I/O routines**
  These routines require a USE IFPORT statement to access the portability library. These routines are only available on Windows* systems on IA-32 processors.

- **Dialog routines**
  These routines require a USE IFLOGM statement to access the dialog library. These routines are only available on Windows* systems.

- **Component Object Module (COM) server routines**
  These routines require a USE IFCOM statement to access the COM library. These routines are only available on Windows* systems.

- **Automation server routines**
  These routines require a USE IFAUTO statement to access the AUTO library. These routines are only available on Windows* systems.
• “Miscellaneous Run-Time Routines”
  Most of these routines require a USE IFCORE statement to obtain the proper interfaces.
  Required USE statements are prominent in the routine descriptions.
  In addition to the appropriate USE statement, for some routines you must specify the types of
  libraries to be used when linking. For more information, see "Specifying Path, Library, and
  Include Directories" in Building Applications.
  Also see "Understanding Errors During the Build Process" in Building Applications.
  In the description of routines, pointers and handles are INTEGER(4) on IA-32 processors;
  INTEGER(8) on Intel® Itanium® processors and IA-32 processors with Intel® Extended
  Memory 64 Technology (Intel® EM64T).

ABORT

Portability Subroutine: Flushes and closes I/O buffers, and terminates program execution.

Module: USE IFPORT

Syntax

CALL ABORT [string]

string

(Input; optional) Character*(*) . Allows you to specify an abort message at program termination.
When ABORT is called, "abort:" is written to external unit 0, followed by string. If omitted, the
default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the
program that launched it.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS LIB

See Also: the EXIT and STOP statements in the Language Reference

Example

USE IFPORT

! The following prints "abort: Fortran Abort Called"
CALL ABORT

! The following prints "abort: Out of here!"
Call ABORT ("Out of here!")
ABOUTBOXQQ

QuickWin Function: Specifies the information displayed in the message box that appears when the user selects the About command from a QuickWin application's Help menu. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

\[
\text{result} = \text{ABOUTBOXQQ} \left( \text{cstring} \right)
\]

cstring

(Input; output) Character*(*). Null-terminated C string.

Results:

The value of the result is INTEGER(4). It is zero if successful; otherwise, nonzero.

If your program does not call ABOUTBOXQQ, the QuickWin run-time library supplies a default string. For further discussion, see "Using QuickWin" in Building Applications.

Compatibility

QUICKWIN GRAPHICS LIB

Example

Consider the following:

USE IFQWIN

INTEGER(4) dummy

! Set the About box message

dummy = ABOUTBOXQQ ('Matrix Multiplier\r\n      Version 1.0'C)

ACCESS

Portability Function: Determines if a file exists and how it can be accessed.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{ACCESS} \left( \text{name, mode} \right)
\]

name

(Input) Character*(*). Name of the file whose accessibility is to be determined.
mode

(Input) Character*(*). Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Tests for read permission</td>
</tr>
<tr>
<td>w</td>
<td>Tests for write permission</td>
</tr>
<tr>
<td>x</td>
<td>Tests for execute permission. On Windows* systems, the extension of name must be .COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.</td>
</tr>
<tr>
<td>(blank)</td>
<td>Tests for existence</td>
</tr>
</tbody>
</table>

The characters within mode can appear in any order or combination. For example, wrx and r are legal forms of mode and represent the same set of inquiries.

Results:
The value of the result is INTEGER(4). It is zero if all inquiries specified by mode are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:

• EACCES: Access denied; the file’s permission setting does not allow the specified access.
• EINVAL: The mode argument is invalid.
• ENOENT: File or path not found.

For a list of error codes, see “IERRNO”.

The name argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “GETFILEINFOQQ”, the INQUIRE statement in the Language Reference

Example

USE IFPORT
! checks for read and write permission on the file "DATAFILE.TXT"
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J
! checks whether "DATAFILE.TXT" is executable. It is not, since
! it does not end in .COM, .EXE, .BAT, or .CMD
J = ACCESS ("DATAFILE.TXT","x")
PRINT *, J

**ALARM**

**Portability Function:** Causes a subroutine to begin execution after a specified amount of time has elapsed.

**Module:** USE IFPORT

**Syntax**

```fortran
result = ALARM (time, proc)
```

* `time` *(Input)* Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when *proc* is to begin execution. If `time` is 0, the alarm is turned off and no routine is called.

* `proc` *(Input)* Name of the procedure to call. The procedure takes no arguments and must be declared **EXTERNAL**.

**Results:**

The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After **ALARM** is called and the timer starts, the calling program continues for `time` seconds. The calling program then suspends and calls *proc*, which runs in another thread. When *proc* finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If *proc* performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries. For more information on multithreading, see "Creating Multithread Applications" in **Building Applications**.

The thread that *proc* runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until *proc* terminates, or is blocked on some other event, such as I/O.

No alarms can occur after the main process ends. If the main program finishes or any thread executes an **EXIT** call, than any pending alarm is deactivated before it has a chance to run.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** "**RUNQQ**"
Example

USE IFPORT
INTEGER(4) numsec, istat
EXTERNAL subprog
numsec = 4
write *, "subprog will begin in ", numsec, " seconds"
ISTAT = ALARM (numsec, subprog)

APPENDMENUQQ

QuickWin Function: Appends a menu item to the end of a menu and registers its callback subroutine. This function is only available on Windows® systems.

Module: USE IFQWIN

Syntax

result = APPENDMENUQQ (menuID, flags, text, routine)

menuID
(Input) INTEGER(4). Identifies the menu to which the item is appended, starting with 1 as the leftmost menu.

flags
(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results below). The following constants are available:

- $MENUGRAYED – Disables and grays out the menu item.
- $MENUDISABLED – Disables but does not gray out the menu item.
- $MENUENABLED – Enables the menu item.
- $MENUSEPARATOR  – Draws a separator bar.
- $MENUCHECKED  – Puts a check by the menu item.
- $MENUUNCHECKED  – Removes the check by the menu item.

text
(Input) Character*(*)}. Menu item name. Must be a null-terminated C string, for example, 'WORDS OF TEXT'C.

routine
(Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:
• WINPRINT – Prints the program.
• WINSAVE – Saves the program.
• WINEXIT – Terminates the program.
• WINSELECTTEXT – Selects text from the current window.
• WINSELECTGRAPHICS – Selects graphics from the current window.
• WINSELECTALL – Selects the entire contents of the current window.
• WININPUT – Brings to the top the child window requesting input and makes it the current window.
• WINCOPY – Copies the selected text and/or graphics from the current window to the Clipboard.
• WINPASTE – Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE – Clears the paste buffer.
• WINSIZETOFIG – Sizes output to fit window.
• WINFULLSCREEN – Displays output in full screen.
• WINSTATE – Toggles between pause and resume states of text output.
• WINCASCADE – Cascades active windows.
• WINTILE – Tiles active windows.
• WINARRANGE – Arranges icons.
• WINSTATUS – Enables a status bar.
• WININDEX – Displays the index for QuickWin help.
• WINUSING – Displays information on how to use Help.
• WINABOUT – Displays information about the current QuickWin application.
• NUL – No callback routine.

Results:
The result type is logical. It is .TRUE. if successful; otherwise, .FALSE..

You do not need to specify a menu item number, because APPENDMENUQQ always adds the new item to the bottom of the menu list. If there is no item yet for a menu, your appended item is treated as the top-level menu item (shown on the menu bar), and text becomes the menu title. APPENDMENUQQ ignores the callback routine for a top-level menu item if there are any other menu items in the menu. In this case, you can set routine to NUL.

If you want to insert a menu item into a menu rather than append to the bottom of the menu list, use INSERTMENUQQ.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUDISABLED. Some combinations do not make sense, such as $MENUDISABLED and $MENUDISABLED, and lead to undefined behavior.
You can create quick-access keys in the text strings you pass to APPENDMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY (ALT+R in the example) as an alternative to selecting the item with the mouse.

For more information about customizing QuickWin menus, see "Using QuickWin" in Building Applications.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "INSERTMENUQQ", "DELETEMENUQQ", "MODIFYMENUFAGLSQQ", "MODIFYMENUROUTINEQQ", "MODIFYMENSTRINGQQ"

Example

USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
...
! Append two items to the bottom of the first (FILE) menu
str = '&Add to File Menu'C ! 'A' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
str = 'Menu Item &2b'C ! '2' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINCASCADE)
! Append an item to the bottom of the second (EDIT) menu
str = 'Add to Second &Menu'C ! 'M' is a quick-access key
result = APPENDMENUQQ(2, $MENUENABLED, str, WINTILE)

ARC, ARC_W

Graphics Functions: Draw elliptical arcs using the current graphics color. These functions are only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = ARC (x1, y1, x2, y2, x3, y3, x4, y4)
result = ARC_W (wx1, wy1, wx2, wy2, wx3, wy3, wx4, wy4)

x1, y1
(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
wx1, y2
(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

x3, y3
(Input) INTEGER(2). Viewport coordinates of start vector.

x4, y4
(Input) INTEGER(2). Viewport coordinates of end vector.

wx1, wy1
(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2
(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

wx3, wy3
(Input) REAL(8). Window coordinates of start vector.

wx4, wy4
(Input) REAL(8). Window coordinates of end vector.

**Results:**
The result type is INTEGER(2). It is nonzero if successful; otherwise, 0. If the arc is clipped or partially out of bounds, the arc is considered successfully drawn and the return is 1. If the arc is drawn completely out of bounds, the return is 0.

The center of the arc is the center of the bounding rectangle defined by the points (x1, y1) and (x2, y2) for ARC and (wx1, wy1) and (wx2, wy2) for ARC_W.

The arc starts where it intersects an imaginary line extending from the center of the arc through (x3, y3) for ARC and (wx3, wy3) for ARC_W. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (x4, y4) for ARC and (wx4, wy4) for ARC_W.

ARC uses the view-coordinate system. ARC_W uses the window-coordinate system. In each case, the arc is drawn using the current color.

**NOTE.** *The ARC routine described here is a QuickWin graphics routine. If you are trying to use the Microsoft*®* Platform SDK version of the Arc routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Arc. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications."
Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

Example
This program draws the arc shown below.

```
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
  x1 = 80;  y1 = 50
  x2 = 240; y2 = 150
  x3 = 120; y3 = 75
  x4 = 90;  y4 = 180
status = ARC( x1, y1, x2, y2, x3, y3, x4, y4 )
END
```

---

**AUTOAddArg**

**AUTO Subroutine:** Passes an argument name and value and adds the argument to the argument list data structure. This subroutine is only available on Windows® systems.

**Modules:** USE IFAUTO, USE IFWINTY

**Syntax**

```
CALL AUTOAddArg (invoke_args, name, value [, intent_arg] [, type])
```

`invoke_args`

The argument list data structure. Must be of type INTEGER(4).

`name`

The argument’s name of type CHARACTER®(*).
**value**
The argument’s value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*) or a single dimension array of one of these types. Can also be of type VARIANT, which is defined in the IFWINTY module.

**intent_arg**
Indicates the intended use of the argument by the called method. Must be one of the following constants defined in the IFAUTO module:

* AUTO_ARG_IN: The argument’s value is read by the called method, but not written. This is the default value if `intent_arg` is not specified.
* AUTO_ARG_OUT: The argument’s value is written by the called method, but not read.
* AUTO_ARG_INOUT: The argument’s value is read and written by the called method.

When the value of `intent_arg` is AUTO_ARG_OUT or AUTO_ARG_INOUT, the variable used in the `value` parameter should be declared using the VOLATILE attribute. This is because the value of the variable will be changed by the subsequent call to AUTOInvoke. The compiler’s global optimizations need to know that the value can change unexpectedly.

**type**
The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_VARIANT</td>
<td>TYPE(VARIANT)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

See Also: “AUTOInvoke”, the VOLATILE attribute in the Language Reference
Example
See the example in “COMInitialize”.

AUTOAllocateInvokeArgs

**AUTO Function:** Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke. This function is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**

```
result = AUTOAllocateInvokeArgs()
```

**Results:**
The value returned is an argument list data structure of type INTEGER(4).

**See Also:** “AUTOInvoke”

**Example**
See the example in “COMInitialize”.

AUTODEallocateInvokeArgs

**AUTO Subroutine:** Deallocates an argument list data structure. This subroutine is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**

```
CALL AUTODEallocateInvokeArgs(invoke_args)
```

`invoke_args`
The argument list data structure. Must be of type INTEGER(4).

**Example**
See the example in “COMInitialize”.

AUTOGetExceptInfo

**AUTO Subroutine:** Retrieves the exception information when a method has returned an exception status. This subroutine is only available on Windows* systems.

**Module:** USE IFAUTO
**Syntax**

```
CALL AUTOGetExceptInfo (invoke_args, code, source, description, h_file, h_context, scode)
```

*invoke_args*

The argument list data structure. Must be of type INTEGER(4).

*code*

An output argument that returns the error code. Must be of type INTEGER(2).

*source*

An output argument that returns a human-readable name of the source of the exception. Must be of type CHARACTER*(*)

*description*

An output argument that returns a human-readable description of the error. Must be of type CHARACTER*(*)

*h_file*

An output argument that returns the fully qualified path of a Help file with more information about the error. Must be of type CHARACTER*(*)

*h_context*

An output argument that returns the Help context of the topic within the Help file. Must be of type INTEGER(4).

*scode*

An output argument that returns an SCODE describing the error. Must be of type INTEGER(4).

---

**AUTOGetProperty**

**AUTO Function:** Passes the name or identifier of the property and gets the value of the automation object’s property. This function is only available on Windows* systems.

**Modules:** USE IFAUTO, USE IFWINTY

**Syntax**

```
result = AUTOGetProperty (idispatch, id, value [, type])
```

*idispatch*

The object’s IDispatch interface pointer. Must be of type INTEGER(4).

*id*

The argument’s name of type CHARACTER*(*) or its member ID of type INTEGER(4).
value
An output argument that returns the argument’s value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*) or a single dimension array of one of these types.

type
The variant type of the requested argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

Results:
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOGetPropertyByID**

**AUTO Function:** Passes the member ID of the property and gets the value of the automation object's property into the argument list's first argument. This function is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**

result = AUTOGetPropertyByID (idispatch, memid, invoke_args)

**idispatch**
The object’s IDispatch interface pointer. Must be of type INTEGER(4).
**memid**
Member ID of the property. Must be of type INTEGER(4).

**invoke_args**
The argument list data structure. Must be of type INTEGER(4).

**Results:**
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

### AUTOGetPropertyInvokeArgs

**AUTO Function:** Passes an argument list data structure and gets the value of the automation object’s property specified in the argument list’s first argument. This function is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**
```
result = AUTOGetPropertyInvokeArgs (idispatch, invoke_args)
```

**dispath**
The object’s IDispatch interface pointer. Must be of type INTEGER(4).

**invoke_args**
The argument list data structure. Must be of type INTEGER(4).

**Results:**
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

### AUTOInvoke

**AUTO Function:** Passes the name or identifier of an object’s method and an argument list data structure and invokes the method with the passed arguments. This function is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**
```
result = AUTOInvoke (idispatch, id, invoke_args)
```

**idispatch**
The object’s IDispatch interface pointer. Must be of type INTEGER(4).
id
The argument’s name of type CHARACTER*(*) or its member ID of type INTEGER(4).

invoke_args
The argument list data structure. Must be of type INTEGER(4).

Results:
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

Example
See the example in “COMInitialize”.

AUTOSetProperty

AUTO Function: Passes the name or identifier of the property and a value, and sets the value of the automation object’s property. This function is only available on Windows* systems.

Module: USE IFAUTO, USE IFWINTY

Syntax

result = AUTOSetProperty (idispatch, id, value [, type])

idispatch
The object’s IDispatch interface pointer. Must be of type INTEGER(4).

id
The argument’s name of type CHARACTER*(*) or its member ID of type INTEGER(4).

value
The argument’s value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*) or a single dimension array of one of these types.

type
The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>
Results:
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOSetPropertyByID**

**AUTO Function:** Passes the member ID of the property and sets the value of the automation object’s property into the argument list’s first argument. This function is only available on Windows* systems.

**Module:** USE IFAUTO

**Syntax**

```
result = AUTOSetPropertyByID (idispatch, memid, invoke_args)
```

*idispatch*

The object’s IDispatch interface pointer. Must be of type INTEGER(4).

*memid*

Member ID of the property. Must be of type INTEGER(4).

*invoke_args*

The argument list data structure. Must be of type INTEGER(4).

**Results:**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOSetPropertyInvokeArgs**

**AUTO Function:** Passes an argument list data structure and sets the value of the automation object’s property specified in the argument list’s first argument. This function is only available on Windows* systems.

Module: USE IFAUTO

Syntax

\[ \text{result} = \text{AUTOSetPropertyInvokeArgs} \left( \text{idispatch, invoke_args} \right) \]

idispatch
The object’s IDispatch interface pointer. Must be of type INTEGER(4).

invoke_args
The argument list data structure. Must be of type INTEGER(4).

Results:
Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

BEEPQQ

Portability Subroutine: Sounds the speaker at the specified frequency for the specified duration in milliseconds.

Module: USE IFPORT

Syntax

\[ \text{CALL BEEPQQ} \left( \text{frequency, duration} \right) \]

frequency
(Input) INTEGER(4). Frequency of the tone in Hz.

duration
(Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “SLEEPQQ”

Example

USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration = 1000
CALL BEEPQQ(frequency, duration)
BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

Portability Functions: Compute the single-precision values of Bessel functions of the first and second kinds.

Module: USE IFPORT

Syntax

\[
\begin{align*}
\text{result} & = \text{BESJ0} (\text{value}) \\
\text{result} & = \text{BESJ1} (\text{value}) \\
\text{result} & = \text{BESJN} (n, \text{value}) \\
\text{result} & = \text{BESY0} (\text{posvalue}) \\
\text{result} & = \text{BESY1} (\text{posvalue}) \\
\text{result} & = \text{BESYN} (n, \text{posvalue})
\end{align*}
\]

\text{value} (Input) REAL(4). Independent variable for a Bessel function.

\text{n} (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.

\text{posvalue} (Input) REAL(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results:

BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and \text{n}, respectively, with the independent variable \text{posvalue}.

BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and \text{n}, respectively, with the independent variable \text{posvalue}.

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.

Bessel functions are explained more fully in most mathematics reference books, such as the Handbook of Mathematical Functions (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN”
BIC, BIS

Portability Subroutines: Perform a bit-level set and clear for integers.

Module: USE IFPORT

Syntax

CALL BIC (bitnum, target)
CALL BIS (bitnum, target)

bitnum
(Input) INTEGER(4). Bit number to set. Must be in the range 0 (least significant bit) to 31 (most significant bit) if target is INTEGER(4). If target is INTEGER(8), bitnum must be in range 0 to 63.

target
(Input; output) INTEGER(4) or INTEGER(8). Variable whose bit is to be set.

BIC sets bit bitnum of target to 0; BIS sets bit bitnum to 1.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “BIT”

Example

Consider the following:

USE IFPORT
integer(4) bitnum, target_i4
integer(8) target_i8

target_i4 = Z'AAAA'
bitnum = 1
call BIC(bitnum, target_i4)
target_i8 = Z'FFFFFFFF00000000'
bitnum = 40
call BIC(bitnum, target_i8)
bitnum = 0
call BIS(bitnum, target_i4)
bitnum = 1
call BIS(bitnum, target_i8)
print '(" integer*4 result ",Z)', target_i4
print '(" integer*8 result ",Z)', target_i8
end
**BIT**

**Portability Function:** Performs a bit-level test for integers.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{BIT}(\text{bitnum}, \text{source})
\]

**bitnum**

(Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).

**source**

(Input) INTEGER(4) or INTEGER(8). Variable being tested.

**Results:**

The result type is logical. It is .TRUE. if bit \text{bitnum} of \text{source} is 1; otherwise, .FALSE..

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** “BIC, BIS”

**BSEARCHQQ**

**Portability Function:** Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{BSEARCHQQ}(\text{adrkey}, \text{adrarray}, \text{length}, \text{size})
\]

**adrkey**

(Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel® Itanium® and Intel® EM64T processors. Address of the variable containing the element to be found (returned by LOC).

**adrarray**

(Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Address of the array (returned by LOC).

**length**

(Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Number of elements in the array.
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in `IFPORT.F90`, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**Results:**

The result type is INTEGER(4). It is an array index of the matched entry, or 0 if the entry is not found.

The array must be sorted in ascending order before being searched.

---

**CAUTION.** The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the length and size arguments are correct, and that size is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “SORTQQ”, the LOC intrinsic function in the *Language Reference*
Example
USE IFPORT
INTEGER(4) array(10), length
INTEGER(4) result, target
length = SIZE(array)
...
result = BSEARCHQQ(LOC(target),LOC(array),length,SRT$INTEGER4)

CDFLOAT

Portability Function: Converts a COMPLEX(4) argument to double-precision real type.
Module: USE IFPORT
Syntax
   result = CDFLOAT(input)
input
(Input) COMPLEX(4). The value to be converted.
Results:
The result type is REAL(8).
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

CHANGEDIRQQ

Portability Function: Makes the specified directory the current, default directory.
Module: USE IFPORT
Syntax
   result = CHANGEDIRQQ(dir)
dir
(Input) Character*(*). Directory to be made the current directory.
Results:
The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..
If you do not specify a drive in the dir string, the named directory on the current drive becomes the current directory. If you specify a drive in dir, the named directory on the specified drive becomes the current directory.
CHANGEDRIVEQQ

Portability Function: Makes the specified drive the current, default drive.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{CHANGEDRIVEQQ} (\text{drive})
\]

\text{drive}

(Input) Character*(*) String beginning with the drive letter.

Results:
The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE. On Linux* and Mac OS* systems, the result is always .FALSE..

Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of \text{drive}. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “GETDRIVESQQ”, “MAKEDIRQQ”, “DELDIRQQ”, “CHANGEDRIVEQQ”

Examples

USE IFPORT

LOGICAL(4) status

status = CHANGEDRIVEQQ('d')

Consider the following:

USE IFPORT
LOGICAL(4) CHANGEDIT
CHANGEDIT = CHANGEDRIVEQQ('d')
IF (CHANGEDIT) THEN
   PRINT *, 'CHANGEDRIVEQQ SUCCESSFUL'
ELSE
   PRINT *, 'Drive could not be changed'
ENDIF
END

CHDIR

Portability Function: Changes the default directory.
Module: USE IFPORT
Syntax
   result = CHDIR (dir_name)

   dir_name
     (Input) Character*(*) Name of a directory to become the default directory.

Results:
The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:
• ENOENT: The named directory does not exist.
• ENOTDIR: The dir_name parameter is not a directory.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB
See Also: “CHANGEDRIRQQ”
Examples
   use ifport
   integer(4) istatus, enoent, enotdir
   character(255) newdir
   character(300) prompt, errmsg
   prompt = 'Please enter directory name: '
   10 write(*,*) TRIM(prompt)
   read *, newdir
   ISTATUS = CHDIR(newdir)
   select case (istatus)
case (2)  ! ENOENT
    errmsg = 'The directory '//TRIM(newdir)//' does not exist'
end select
write (errmsg,*) 'Error with code ', istatus
end select
write(*,*) TRIM(errmsg)
goto 10
40    write(*,*) 'Default directory successfully changed.'
end

The following shows another example:

USE IFPORT
CHARACTER(LEN=16) NEW_DIRECTORY
LOGICAL(4) CHANGEDIT
NEW_DIRECTORY='c:\program files'
CHANGEDIT=CHDIR(NEW_DIRECTORY)
IF (CHANGEDIT) THEN
    PRINT *, 'CHDIR SUCCESSFUL'
ELSE
    PRINT *, 'Directory could not be changed'
ENDIF
END

CHMOD

Portability Function: Changes the access mode of a file.
Module: USE IFPORT
Syntax
    result = CHMOD (name, mode)
name
(Input) Character*(*) . Name of the file whose access mode is to be changed. Must have a single path.
mode

(Input) Character*(*) File permission: either Read, Write, or Execute. The mode parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

<table>
<thead>
<tr>
<th>Permission Bit</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>4000</td>
<td>Set user ID on execution</td>
<td>W<em>32, W</em>64: Ignored; never true L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>2000</td>
<td>Set group ID on execution</td>
<td>W<em>32, W</em>64: Ignored; never true L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>1000</td>
<td>Sticky bit</td>
<td>W<em>32, W</em>64: Ignored; never true L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>0400</td>
<td>Read by owner</td>
<td>W<em>32, W</em>64: Ignored; always true L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>0200</td>
<td>Write by owner</td>
<td>Settable</td>
</tr>
<tr>
<td>0100</td>
<td>Execute by owner</td>
<td>W<em>32, W</em>64: Ignored; based on file name extension L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>0040, 0020, 0010</td>
<td>Read, Write, Execute by group</td>
<td>W<em>32, W</em>64: Ignored; assumes owner permissions L<em>X, M</em>X32: Settable</td>
</tr>
<tr>
<td>0004, 0002, 0001</td>
<td>Read, Write, Execute by others</td>
<td>W<em>32, W</em>64: Ignored; assumes owner permissions L<em>X, M</em>X32: Settable</td>
</tr>
</tbody>
</table>

The following regular expression represents a symbolic mode:

```
[ugo][+--][rwxXst]*
```

"[ugo]" is ignored on Windows systems. On Linux and Mac OS systems, a combination of the letters "ugo" control which users’ access to the file will be changed:

- u: The user who owns the file
- g: Other users in the group that owns the file
- o: Other users not in the group that owns the file
- a: All users

"[+ - =]" indicates the operation to carry out:

- +: Add the permission
- -: Remove the permission
- =: Absolutely set the permission
"[rwxXst]" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux and Mac OS systems, all letters are significant.

Results:
The result type is INTEGER(4). The result is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:
• ENOENT: The specified file was not found.
• EINVAL: The mode argument is invalid.
• EPERM: Permission denied; the file's mode cannot be changed.

Example
USE IFPORT
integer(4) I,Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (i) then
   ISTATUS = CHMOD ("datafile.txt", "+w")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, i

CLEARSSCREEN

Graphics Subroutine: Erases the target area and fills it with the current background color. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax
   CALL CLEARSCREEN (area)

area
(Input) INTEGER(4). Identifies the target area. Must be one of the following symbolic constants (defined in IFQWIN.F90):
• $GCLEARSCREEN - Clears the entire screen.
• $GVIEWPORT  - Clears only the current viewport.
• $GWINDOW    - Clears only the current text window (set with SETTEXTWINDOW).
All pixels in the target area are set to the color specified with SETBKCOLORRGB. The default color is black.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** GETBKCOLORRGB, SETBKCOLORRGB, SETTEXTWINDOW, SETVIEWPORT

**Example**

USE IFQWIN
CALL CLEARSCREEN ($GCLEARSCREEN)

## CLEARSTATUSFPQQ

**Portability Subroutine:** Clears the exception flags in the floating-point processor status word.

**Module:** USE IFPORT

**Syntax**

CALL CLEARSTATUSFPQQ ( )

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Visual Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see "The Floating-Point Environment" in Building Applications.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** GETSTATUSFPQQ, SETCONTROLFPQQ, GETCONTROLFPQQ, SIGNALQQ

**Example**

! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a floating-point exception has occurred.
! So, build this console application with the default floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows)
! or -O0 (Linux) to get the correct results
!
PROGRAM CLEARFP
USE IFPORT
REAL*4 A,B,C
INTEGER*2 STS
A = 2.0E0
B = 0.0E0
! Poll and display initial floating point status
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS
! Cause a divide-by-zero exception
! Poll and display the new floating point status
C = A/B
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS
! If a divide by zero error occurred, clear the floating point
! status register so future exceptions can be detected.
IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
   CALL CLEARSTATUSFPQQ()
   CALL GETSTATUSFPQQ(STS)
   WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
ENDIF
END

CLICKMENUQQ

QuickWin Function: Simulates the effect of clicking or selecting a menu command. The
QuickWin application responds as though the user had clicked or selected the command. This
function is only available on Windows® systems.
Module: USE IFQWIN
Syntax
   result = CLICKMENUQQ (item)
item

(Input) INTEGER(4). Constant that represents the command selected from the Window menu. Must be one of the following symbolic constants (defined in IFQWIN.F90):

• QWIN$STATUS - Status command
• QWIN$TILE - Tile command
• QWIN$CASCADE - Cascade command
• QWIN$ARRANGE - Arrange Icons command

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "REGISTERMOUSEEVENT", "UNREGISTERMOUSEEVENT", "WAITONMOUSEEVENT", "Using QuickWin" in Building Applications

CLOCK

Portability Function: Converts a system time into an 8-character ASCII string.

Module: USE IFPORT

Syntax

result = CLOCK ( )

Results:
The result type is character with a length of 8. The result is the current time in the form hh:mm:ss, using a 24-hour clock.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference

Example

USE IFPORT
character(8) whatimeisit
whatimeisit = CLOCK ()
print *, 'The current time is ', whatimeisit
CLOCKX

**Portability Subroutine:** Returns the processor clock to the nearest microsecond.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL CLOCKX (clock)
```

`clock`

(Input) REAL(8). The current time.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

COMAddObjectReference

**COM Function:** Adds a reference to an object’s interface. This function is only available on Windows® systems.

**Module:** USE IFCOM

**Syntax**

```fortran
result = COMAddObjectReference (iunknown)
```

`iunknown`

An IUnKnown interface pointer. Must be of type INTEGER(4).

**Results:**

The result type is INTEGER(4). It is the object’s current reference count.

COMCLSIDFromProgID

**COM Subroutine:** Passes a programmatic identifier and returns the corresponding class identifier. This subroutine is only available on Windows® systems.

**Modules:** USE IFCOM, USE IFWINTY

**Syntax**

```fortran
CALL COMCLSIDFromProgID (prog_id, clsid, status)
```

`prog_id`

The programmatic identifier of type CHARACTER*(*).
** COMCLSIDFromString **

**COM Subroutine:** Passes a class identifier string and returns the corresponding class identifier. This subroutine is only available on Windows* systems on systems.

**Modules:** USE IFCOM, USE IFWINTY

**Syntax**

```plaintext
CALL COMCLSIDFromString (string, clsid, status)
```

*string*

The class identifier string of type CHARACTER*(*)().

*clsid*

The class identifier corresponding to the identifier string. Must be of type GUID, which is defined in the IFWINTY module.

*status*

The status of the operation. It can be any status returned by CLSIDFromProgID (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

** COMCreateObjectByGUID **

**COM Subroutine:** Passes a class identifier, creates an instance of an object, and returns a pointer to the object’s interface. This subroutine is only available on Windows* systems.

**Modules:** USE IFCOM, USE IFWINTY

**Syntax**

```plaintext
CALL COMCreateObjectByGUID (clsid, clsctx, iid, interface, status)
```

*clsid*

The class identifier of the class of object to be created. Must be of type GUID, which is defined in the IFWINTY module.
COMCreateObjectByProgID

**COM Subroutine:** Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object’s IDispatch interface. This subroutine is only available on Windows* systems.

**Module:** USE IFCOM

**Syntax**

```fortran
CALL COMCreateObjectByProgID (prog_id, idispatch, status)
```

**prog_id**
The programmatic identifier of type CHARACTER*(*)

**idispatch**
An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(4).

**status**
The status of the operation. It can be any status returned by CLSIDFromProgID or CoCreateInstance (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

COMGetActiveObjectByGUID

**COM Subroutine:** Passes a class identifier and returns a pointer to the interface of a currently active object. This subroutine is only available on Windows* systems.

**Module:** USE IFCOM, USE IFWINTY
Syntax
CALL COMGetActiveObjectByGUID (clsid, iid, interface, status)

clsid
The class identifier of the class of object to be found. Must be of type GUID, which is defined in the IFWINTY module.

iid
The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

interface
An output argument that returns the object’s interface pointer. Must be of type INTEGER(4).

status
The status of the operation. It can be any status returned by GetActiveObject (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

COMGetActiveObjectByProgID

COM Subroutine: Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object. This subroutine is only available on Windows* systems.

Module: USE IFCOM

Syntax
CALL COMGetActiveObjectByProgID (prog_id, idispatch, status)

prog_id
The programmatic identifier of type CHARACTER*(*)

idispatch
An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(4).

status
The status of the operation. It can be any status returned by CLSIDFromProgID or GetActiveObject (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

Example
See the example in “COMInitialize”.
COMGetFileObject

COM Subroutine: Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file. This subroutine is only available on Windows* systems.

Module: USE IFCOM

Syntax

CALL COMGetFileObject (filename, idispatch, status)

filename
The path of the file of type CHARACTER(*).

idispatch
An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(4).

status
The status of the operation. It can be any status returned by the CreateBindCtx or MkParseDisplayName routines, or the IMoniker::BindToObject method (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

COMInitialize

COM Subroutine: Initializes the COM library. This subroutine is only available on Windows* systems.

Module: USE IFCOM

Syntax

CALL COMInitialize (status)

status
The status of the operation. It can be any status returned by OleInitialize (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

You must use this routine to initialize the COM library before calling any other COM or AUTO routine.

Example

program COMExample

use ifwin
use ifcom
use ifauto

    implicit none

! Variables
integer(4) word_app
integer(4) status
integer(4) invoke_args

call COMInitialize(status)

! Call GetActiveObject to get a reference to a running MS WORD ! application
    call COMGetActiveObjectByProgID("Word.Application", word_app, status)
if (status >= 0) then
    ! Print the active document
    invoke_args = AutoAllocateInvokeArgs()
    call AutoAddArg(invoke_args, "Copies", 2)
    status = AutoInvoke(word_app, "PrintOut", invoke_args)
    call AutoDeallocateInvokeArgs(invoke_args)
    ! Release the reference
    status = COMReleaseObject(word_app)
end if

call COMUninitialize()

end program

COMIsEqualGUID

COM Function: Determines whether two globally unique identifiers (GUIDs) are the same. This function is only available on Windows® systems.

Modules: USE IFCOM, USE IFWINTY

Syntax
    result = COMIsEqualGUID (guid1, guid2)

guid1
The first GUID. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).
guid2
The second GUID, which will be compared to guid1. It must be the same type of GUID as guid1. For example, if guid1 is a CLSID, guid2 must also be a CLSID.

Results:
The result type is LOGICAL(4). The result is .TRUE. if the two GUIDs are the same; otherwise, .FALSE.

**COMMITQQ**

Run-time Function: Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file’s physical device.

Module: USE IFCORE

Syntax

```
result = COMMITQQ (unit)
```

unit
(Input) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

Results:
The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initially written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.

COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the PRINT and WRITE statements in the *Language Reference*
**Example**

USE IFCORE
INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff
OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')
DO WHILE (.TRUE.)
  WRITE (*, '(A, ")') 'Enter some data (Hit RETURN to &
exit): '

  len = GETSTRQQ (stuff)
  IF (len .EQ. 0) EXIT
  WRITE (unit, *) stuff
  IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
END DO
CLOSE (unit)
END

**COMPLINT, COMPLREAL, COMPLLOG**

**Portability Functions:** Return a BIT-WISE complement or logical .NOT. of the argument.

**Module:** USE IFPORT

**Syntax**

```
  result = COMPLINT (intval)
  result = COMPLREAL (realval)
  result = COMPLLOG (logval)
```

*intval*
(Input) INTEGER(4).

*realval*
(Input) REAL(4).

*logval*
(Input) LOGICAL(4).

**Results:**

If the argument is logical, the result is logical. Otherwise, the result is Boolean (a CRAY* bitset).
With a Boolean result, use a BIT-WISE complement. For the logical COMPLLOG, just toggle 1<-->0.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**COMQueryInterface**

**COM Subroutine:** Passes an interface identifier and returns a pointer to an object’s interface. This subroutine is only available on Windows* systems.

**Modules:** USE IFCOM, USE IFWINTY

**Syntax**

```fortran
CALL COMQueryInterface (iunknown, iid, interface, status)
```

- `iunknown`:
  An IUnknown interface pointer. Must be of type INTEGER(4).

- `iid`:
  The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.

- `interface`:
  An output argument that returns the object’s interface pointer. Must be of type INTEGER(4).

- `status`:
  The status of the operation. It can be any status returned by the IUnknown method QueryInterface (see the Microsoft* Platform SDK). Must be of type INTEGER(4).

**COMReleaseObject**

**COM Function:** Indicates that the program is done with a reference to an object’s interface. This function is only available on Windows* systems.

**Module:** USE IFCOM

**Syntax**

```fortran
result = COMReleaseObject (iunknown)
```

- `iunknown`:
  An IUnknown interface pointer. Must be of type INTEGER(4).

**Results:**

The result type is INTEGER(4). It is the object’s current reference count.
Example
See the example in “COMInitialize”.

**COMStringFromGUID**

**COM Subroutine:** Passes a globally unique identifier (GUID) and returns a string of printable characters. This subroutine is only available on Windows* systems.

**Modules:** USE IFCOM, USE IFWINTY

**Syntax**

```plaintext
CALL COMStringFromGUID (guid, string, status)
```

**guid**
The GUID to be converted. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

**string**
A character variable of type CHARACTER(*) that receives the string representation of the GUID. The length of the character variable should be at least 38.

**status**
The status of the operation. If the string is too small to contain the string representation of the GUID, the value is zero. Otherwise, the value is the number of characters in the string representation of the GUID. Must be of type INTEGER(4).

The string representation of a GUID has a format like that of the following:

```
{c200e360-38c5-11ce-ae62-08002b2b79ef}
```

where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

**COMUninitialize**

**COM Subroutine:** Uninitializes the COM library. This subroutine is only available on Windows* systems.

**Module:** USE IFCOM

**Syntax**

```plaintext
CALL COMUninitialize ( )
```

When using COM routines, this must be the last routine called.
Example
See the example in “COMInitialize”.

CSMG

Portability Function: Performs an effective BIT-WISE store under mask.
Module: USE IFPORT
Syntax
result = CSMG (x, y, z)
x, y, z
(Input) INTEGER(4).
Results:
The result type is INTEGER(4). The result is equal to the following expression:

\[(x \& z) \mid (y \& \neg z)\]

where "&" is a bitwise AND operation, | - bitwise OR, ~ - bitwise NOT.
The function returns the value based on the following rule: when a bit in \(z\) is 1, the output bit is taken from \(x\). When a bit in \(z\) is zero, the corresponding output bit is taken from \(y\).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

CTIME

Portability Function: Converts a system time into a 24-character ASCII string.
Module: USE IFPORT
Syntax
result = CTIME (stime)
stime
(Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.
Results:
The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.
The value of \(stime\) can be determined by calling the TIME function. CTIME(TIME( )) returns the current time and date.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference

Example
USE IFPORT
character (24) systime
systime = CTIME (TIME( ))
print *, 'Current date and time is ', systime

DATE

Portability Function or Subroutine: Returns the current system date.
Module: USE IFPORT
Function Syntax:
   result = DATE ( )
Subroutine Syntax:
   CALL DATE (string)
string
(Output) CHARACTER. Variable or array containing at least nine bytes of storage.
DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where
mm, dd, and yy are two-digit representations of the month, day, and year, respectively.
DATE in its subroutine form returns string in the form dd-mmm-yy, where dd is a two-digit
representation of the current day of the month, mmm is a three-character abbreviation for the
current month (for example, Jan) and yy are the last two digits of the current year.

NOTE. DATE is an intrinsic procedure unless you specify USE IFPORT.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the DATE subroutine in the Language Reference

Example
USE IFPORT
!If today's date is March 02, 2000, the following
!code prints "02-Mar-00"
CHARACTER(9) TODAY
CALL DATE(TODAY)
PRINT *, Today
!The next line prints "03/02/00"
PRINT *, DATE()

**DATE4**

**Portability Subroutine:** Returns the current system date.

**Module:** USE IFPORT

**Syntax**

```
CALL DATE4 (datestr)
```

`datestr`

(Output) CHARACTER.

This subroutine returns `datestr` in the form dd-mmm-yyyy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yyyy are the four digits of the current year.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN**

**Portability Functions:** Compute the double-precision values of Bessel functions of the first and second kinds.

**Module:** USE IFPORT

**Syntax**

```
result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)
```

`value`

(Input) REAL(8). Independent variable for a Bessel function.
$n$

(Input) Integer. Specifies the order of the selected Bessel function computation.

$posvalue$

(Input) REAL(8). Independent variable for a Bessel function. Must be greater than or equal to zero.

**Results:**

DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and $n$, respectively, with the independent variable $posvalue$.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and $n$, respectively, with the independent variable $posvalue$.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** “BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN”

**Example**

```fortran
USE IFPORT
real(8) besnum, besout
10 read *, besnum
   besout = dbesj0(besnum)
   print *, 'result is ',besout
   goto 10
end
```

**DCLOCK**

**Portability Function:** Returns the elapsed time in seconds since the start of the current process.

**Module:** USE IFPORT

**Syntax**

```
result = DCLOCK ( )
```
Results:
The result type is REAL(8). This routine provides accurate timing to the nearest microsecond, taking into account the frequency of the processor where the current process is running. You can obtain equivalent results using standard Fortran by using the CPU_TIME intrinsic subroutine.

Note that the first call to DCLOCK performs calibration.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the DATE_AND_TIME and CPU_TIME subroutines in the Language Reference

Example
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME, DCLOCK
EXTERNAL DCLOCK
START_CLOCK = DCLOCK()
CALL FOO()
STOP_CLOCK = DCLOCK()
PRINT *, 'foo took:', STOP_CLOCK - START_CLOCK, 'seconds.'

DELDIRQQ

Portability Function: Deletes a specified directory.

Module: USE IFPORT

Syntax

result = DELDIRQQ (dir)

(dir)

(Input) Character(*). String containing the path of the directory to be deleted.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “GETDRIVEDIRQQ”, “MAKEDIRQQ”, “CHANGEDIRQQ”, “CHANGEDRIVEQQ”, “UNLINK”
DELETEMENUQQ

**QuickWin Function:** Deletes a menu item from a QuickWin menu. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

result = DELETEMENUQQ (menuID, itemID)

**menuID**
(Input) INTEGER(4). Identifies the menu that contains the menu item to be deleted, starting with 1 as the leftmost menu.

**itemID**
(Input) INTEGER(4). Identifies the menu item to be deleted, starting with 0 as the top menu item.

**Results:**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

**Compatibility**
QUICKWIN GRAPHICS LIB

**See Also:** "APPENDMENUQQ", "INSERTMENUQQ", "MODIFYMENFLAGSQL", "MODIFYMENROUTINEQQ", "MODIFYMENSTRINGQQ", "Using QuickWin" in *Building Applications*

**Example**

USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
str = 'Add to EDIT Menu'C   ! Append to 2nd menu
result = APPENDMENUQQ(2, $MENUENABLED, str, WINSTATUS)
! Delete third item (EXIT) from menu 1 (FILE)
result = DELETEMENUQQ(1, 3)
! Delete entire fifth menu (WINDOW)
result = DELETEMENUQQ(5, 0)
END

DELFFILESQQ

**Portability Function:** Deletes all files matching the name specification, which can contain wildcards (* and ?).
Module: USE IFPORT

Syntax

\[
\text{result} = \text{DELFILESQQ} \ (\text{files})
\]

files

(Input) Character*(*) Files to be deleted. Can contain wildcards (* and ?).

Results:

The result type is INTEGER(2). The result is the number of files deleted.

You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “FINDFILEQQ”

Example

USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: "
len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
   WRITE(*,*) "Are you sure (Y/N)?"
   ch = GETCHARQQ()
   IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END

DFLOATI, DFLOATJ, DFLOATK

Portability Functions: Convert an integer to double-precision real type.

Module: USE IFPORT
**Syntax**

\[
\begin{align*}
\text{result} &= \text{DFLOATI} \ (i) \\
\text{result} &= \text{DFLOATJ} \ (j) \\
\text{result} &= \text{DFLOATK} \ (k)
\end{align*}
\]

\(i\)  
(Input) Must be of type INTEGER(2).

\(j\)  
(Input) Must be of type INTEGER(4).

\(k\)  
(Input) Must be of type INTEGER(8).

**Results:**
The result type is double-precision real (REAL(8) or REAL*8).

**Compatibility**

<table>
<thead>
<tr>
<th>CONSOLE</th>
<th>STANDARD</th>
<th>GRAPHICS</th>
<th>QUICKWIN</th>
<th>GRAPHICS</th>
<th>WINDOWS</th>
<th>LIB</th>
</tr>
</thead>
</table>

See Also: the DFLOAT intrinsic function in the *Language Reference*

---

**DISPLAYCURSOR**

**Graphics Function:** Controls cursor visibility. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

\[
\text{result} = \text{DISPLAYCURSOR} \ (\text{toggle})
\]

\(\text{toggle}\)  
(Input) INTEGER(2). Constant that defines the cursor state. Has two possible values:

- \$GCURSOROFF - Makes the cursor invisible regardless of its current shape and mode.
- \$GCURSORON - Makes the cursor always visible in graphics mode.

**Results:**
The result type is INTEGER(2). The result is the previous value of \(\text{toggle}\).

Cursor settings hold only for the currently active child window. You need to call DISPLAYCURSOR for each window in which you want the cursor to be visible.

A call to SETWINDOWCONFIG turns off the cursor.
DLGEXIT

**Dialog Subroutine:** Closes an open dialog box. This subroutine is only available on Windows* systems.

**Module:** USE IFLOGM

**Syntax**

```
CALL DLGEXIT (dlg)
```

*dlg*  
(Input) Derived type *dialog*. Contains dialog box parameters. The components of the type *dialog* are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

If you want to exit a dialog box on a condition other than the user selecting the OK or Cancel button, you need to include a call to DLGEXIT from within your callback routine. DLGEXIT saves the data associated with the dialog box controls and then closes the dialog box. The dialog box is exited after DLGEXIT has returned control back to the dialog manager, not immediately after the call to DLGEXIT.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:**  "DLGSETRETURN", "DLGINIT, DLGINITWITHRESOURCEHANDLE", "DLGMODAL, DLGMODALWITHPARENT", "DLGMODELESS"

**Example**

```
SUBROUTINE EXITSUB (dlg, exit_button_id, callbacktype)
USE IFLOGM
TYPE (DIALOG) dlg
INTEGER exit_button_id, callbacktype
...
   CALL DLGEXIT (dlg)
```

DLGFLUSH

**Dialog Subroutine:** Updates the display of a dialog box. This subroutine is only available on Windows* systems.
Module: USE IFLOGM

Syntax

CALL DLGFLUSH (dlg [, flushall])

dlg

(Input) Derived type Dialog. Contains dialog box parameters. The components of the type Dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

flushall

(Input; optional) Logical. If .FALSE. (the default), then only the controls that the dialog routines have marked as changed are updated. If .TRUE., all controls are updated with the state of the controls as known by the dialog routines. Normally, you would not set flushall to .TRUE..

When your application calls DLGSET to change a property of a control in a dialog box, the change is not immediately reflected in the displayed dialog box. Changes are applied when the dialog box is first displayed, and then after every dialog callback to the user’s code.

This design expects that, after a call to DLGMODAL or DLGMODELESS, every call to DLGSET will be made from within a callback routine, and that the callback routine finishes quickly. This is true most of the time.

However, there may be cases where you want to change a control outside of a dialog callback, or from within a loop in a dialog callback.

In these cases, DLGFLUSH is required, but is not always sufficient, to update the dialog display. DLGFLUSH sends pending Windows system messages to the dialog box and the controls that it contains. However, many display changes do not appear until after the program reads and processes these messages. A loop that processes the pending messages may be required; for example:

```
use IFWINTY
use IFLOGM
use USER32
logical lNotQuit, lret
integer iRet
TYPE (T_MSG) mesg
lNotQuit = .TRUE.
do while (lNotQuit .AND. (PeekMessage(mesg, 0, 0, 0, PM_NOREMOVE) <> 0))
   lNotQuit = GetMessage(mesg, NULL, 0, 0)
   if (lNotQuit) then
      if (DLGISDLGMESSAGE(mesg) .EQV. .FALSE) then
         lret = TranslateMessage(mesg)
```
iret = DispatchMessage(mesg)
end if
end if
end do

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR

Dialog Functions: Return the state of the dialog control variable. These functions are only available on Windows® systems.

Module: USE IFLOGM

Syntax
result = DLGGET (dlg, controlid, value [, index])
result = DLGGETINT (dlg, controlid, value [, index])
result = DLGGETLOG (dlg, controlid, value [, index])
result = DLGGETCHAR (dlg, controlid, value [, index])

dlg
(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid
(Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

value
(Output) Integer, logical, or character. The value of the control’s variable.

index
(Input; optional) Integer. Specifies the control variable whose value is returned. Necessary if the control has more than one variable of the same data type and you do not want to get the value of the default for that type.
Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGGET functions to return the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variable associated with it, but not necessarily all. The control variables are listed in the table in "Control Indexes" in *Building Applications*. The types of controls they are associated with are listed in the table in "Available Indexes for Each Dialog Control" in *Building Applications*.

You can use DLGGET to return the value of any variable. You can also use DLGGETINT to return an integer value, or DLGGETLOG and DLGGETCHAR to return logical and character values, respectively. If you use DLGGET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to return a variable type that is not available, the DLGGET functions return .FALSE..

If two or more controls have the same controlid, you cannot use these controls in a DLGGET operation. In this case the function returns .FALSE..

The dialog box does not need to be open to access its control variables.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: "DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR", "DLGSETSUB", "DLGINIT, DLGINITWITHRESOURCEHANDLE", "DLGMODAL, DLGMODALWITHPARENT", "DLGMODELESS", "Using Dialog Controls" and "Dialog Controls" in *Building Applications*

Example

USE IFLOGM
INCLUDE "THISDLG.FD"
TYPE (DIALOG)  dlg
INTEGER        val
LOGICAL        retlog, is_checked
CHARACTER(256) text
...
retlog = DLGGET (dlg, IDC_CHECKBOX1, is_checked, dlg_status)
retlog = DLGGET (dlg, IDC_SCROLLBAR2, val, dlg_range)
retlog = DLGGET (dlg, IDC_STATIC_TEXT1, text, dlg_title)
...
DLGINIT, DLGINITWITHRESOURCEHANDLE

Dialog Functions: Initialize a dialog box. These functions are only available on Windows* systems.

Module: USE IFLOGM

Syntax

result = DLGINIT (id, dlg)
result = DLGINITWITHRESOURCEHANDLE (id, hinst, dlg)

id
(Input) INTEGER(4). Dialog identifier. Can be either the symbolic name for the dialog or the
identifier number, both listed in the Include file (with extension .FD).

dlg
(Output) Derived type dialog. Contains dialog box parameters.

hinst
(Input) INTEGER(4). Module instance handle in which the dialog resource can be found.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is
.FALSE..

DLGINIT must be called to initialize a dialog box before it can be used with DLGMODAL,
DLGMODELESS, or any other dialog function.

DLGINIT will only search for the dialog box resource in the main application. For example, it will
not find a dialog box resource that has been built into a dynamic link library.

DLGINITWITHRESOURCEHANDLE can be used when the dialog resource is not in the main
application. If the dialog resource is in a dynamic link library (DLL), hinst must be the value
passed as the first argument to the DLLMAIN procedure.

Dialogs can be used from any application, including console, QuickWin, and Windows
applications.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

...
retlog = DLGINIT (IDD_DLG3, thisdlg)
IF (.not. retlog) THEN
  WRITE (*,*) 'ERROR: dialog not found'
ELSE
...

**DLGISDLGMESSEGE, DLGISDLGMESSEGEWITHDLG**

**Dialog Functions:** Determine whether the specified message is intended for one of the currently displayed modeless dialog boxes, or a specific dialog box. These functions are only available on Windows* systems.

**Module:** USE IFLOGM

**Syntax**

result = DLGISDLGMESSEGE (mesg)
result = DLGISDLGMESSEGEWITHDLG (mesg, dlg)

*mesg*

(Input) Derived type T_MSG. Contains a Windows message.

*dll*

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if the message is processed by the dialog box. Otherwise, the result is .FALSE. and the message should be further processed.

DLGISDLGMESSEGE must be called in the message loop of Windows applications that display a modeless dialog box using DLGMODELESS. DLGISDLGMESSEGE determines whether the message is intended for one of the currently displayed modeless dialog boxes. If it is, it passes the message to the dialog box to be processed.

DLGISDLGMESSEGEWITHDLG specifies a particular dialog box to check. Use DLGISDLGMESSEGEWITHDLG when the message loop is in a main application and the currently active modeless dialog box was created by a DLL.

**Compatibility**

WINDOWS
See Also: "DLGMODELESS", "Using a Modeless Dialog Box" in Building Applications

Example

use IFLOGM
include 'resource.fd'
type (DIALOG) dlg
type (T.MSG) mesg
integer*4 ret
logical*4 ret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) )
  ! Note that DlgIsDlgMessage must be called in order to give
  ! the dialog box first chance at the message.
  if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
    lret = TranslateMessage( mesg )
    ret  = DispatchMessage( mesg )
  end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return

DLGMODAL, DLGMODALWITHPARENT

Dialog Functions: Display a dialog box and process user control selections made within the box. These functions are only available on Windows* systems.

Module: USE IFLOGM

Syntax
result = DLGMODAL (dlg)
result = DLGMODALWITHPARENT (dlg, hwndParent)
**dlg**

(Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

**hwndParent**

(Input) Integer. Specifies the parent window for the dialog box. If omitted, the value is determined in this order:

1. If DLGMODAL is called from the callback of a modal or modeless dialog box, then that dialog box is the parent window.
2. If it is a QuickWin or Standard Graphics application, then the frame window is the parent window.
3. The Windows desktop window is the parent window.

**Results:**

The result type is INTEGER(4). By default, if successful, it returns the identifier of the control that caused the dialog to exit; otherwise, it returns -1. The return value can be changed with the DLGSETRETURN subroutine.

During execution, DLGMODAL displays a dialog box and then waits for user control selections. When a control selection is made, the callback routine, if any, of the selected control (set with DLGSETSUB) is called.

The dialog remains active until an exit control is executed: either the default exit associated with the OK and Cancel buttons, or DLGEXIT within your own control callbacks. DLGMODAL does not return a value until the dialog box is exited.

The default return value for DLGMODAL is the identifier of the control that caused it to exit (for example, IDOK for the OK button and IDCANCEL for the Cancel button). You can specify your own return value with DLGSETRETURN from within one of your dialog control callback routines. You should not specify -1 as your return value, because this is the error value DLGMODAL returns if it cannot open the dialog.

Use DLGMODALWITHPARENT when you want the parent window to be other than the default value (see the definition of hwndParent above). In particular, in an SDI or MDI Windows application, you may want the parent window to be the main application window. The parent window is disabled for user input while the modal dialog box is displayed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** "DLGSETRETURN", "DLGSETSUB", "DLGEXIT", "DLGINIT, DLGINITWITHRESOURCEHANDLE"
Example
USE IFLOGM
INCLUDE "MYDLG.FD"
INTEGER return
TYPE (DIALOG) mydialog
...
return = DLGMODAL (mydialog)
...

DLGMODELESS

Dialog Function: Displays a modeless dialog box. This function is only available on Windows* systems.

Module: USE IFLOGM

Syntax
result = DLGMODELESS (dlg [, nCmdShow, hwndParent])

dlg
(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user. The variable passed to this function must remain in memory for the duration of the dialog box, that is from the DLGINIT call through the DLGUNINIT call.

The variable can be declared as global data in a module, as a variable with the STATIC attribute, or in a calling procedure that is active for the duration of the dialog box. It must not be an AUTOMATIC variable in the procedure that calls DLGMODELESS.

nCmdShow
(Input) Integer. Specifies how the dialog box is to be shown. It must be one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the dialog box.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the dialog box.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
<tr>
<td>SW_SHOW</td>
<td>Activates the dialog box and displays it in its current size and position.</td>
</tr>
</tbody>
</table>
The default value is SW_SHOWNORMAL.

hwndParent
(Input) Integer. Specifies the parent window for the dialog box. The default value is determined in this order:
1. If DLGMODELESS is called from a callback of a modeless dialog box, then that dialog box is the parent window.
2. The Windows desktop window is the parent window.

Results:
The result type is LOGICAL(4). The value is .TRUE. if the function successfully displays the dialog box. Otherwise the result is .FALSE..

During execution, DLGMODELESS displays a modeless dialog box and returns control to the calling application. The dialog box remains active until DLGEXIT is called, either explicitly or as the result of the invocation of a default button callback.

DLGMODELESS is typically used in a Windows application. The application must contain a message loop that processes Windows messages. The message loop must call DLGISDLGMESSAGE for each message (see the example below). Multiple modeless dialog boxes can be displayed at the same time. A modal dialog box can be displayed from a modeless dialog box by calling DLGMODAL from a modeless dialog callback. However, DLGMODELESS cannot be called from a modal dialog box callback.

DLGMODELESS also can be used in a Console, DLL, or LIB project. However, the requirements remain that the application must contain a message loop and must call DLGISDLGMESSAGE for each message. For an example of calling DLGMODELESS in a DLL project, see the Dllprgrs sample in the \SAMPLES\DIALOG folder.
Use the DLG_INIT callback with DLGSETSUB to perform processing immediately after the
dialog box is created and before it is displayed, and to perform processing immediately before the
dialog box is destroyed.

**Compatibility**

WINDOWS  CONSOLE  DLL  LIB

**See Also:** "DLGSETSUB", “DLGINIT, DLGINITWITHRESOURCEHANDLE”, “DLGEXIT”,
“DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG”, "Using a Modeless Dialog Box"
in *Building Applications*

**Example**

```fortran
use IFLOGM
include 'resource.fd'
type (DIALOG)   dlg
type (T_MSG)    mesg
integer*4   ret
logical*4   lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) )
   ! Note that DlgIsDlgMessage must be called in order to give
   ! the dialog box first chance at the message.
   if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
      lret = TranslateMessage( mesg )
      ret  = DispatchMessage( mesg )
   end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return
```
DLGSENDCTRLMESSAGE

**Dialog Function:** Sends a Windows* message to a dialog box control. This function is only available on Windows* systems.

**Module:** USE IFLOGM

**Syntax**

```plaintext
result = DLGSENDCTRLMESSAGE (dlg, controlid, msg, wparam, lparam)
```

- **dlg** *(Input)* Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.
- **controlid** *(Input)* Integer. Specifies the identifier of the control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).
- **msg** *(Input)* Integer. Derived type T_MSG. Specifies the message to be sent.
- **wparam** *(Input)* Integer. Specifies additional message specific information.
- **lparam** *(Input)* Integer. Specifies additional message specific information.

**Results:**
The result type is INTEGER(4). The value specifies the result of the message processing and depends upon the message sent.

The dialog box must be currently active by a call to DLGMODAL or DLGMEMODELESS. This function does not return until the message has been processed by the control.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** “DLGINIT, DLGINITWITHRESOURCEHANDLE”, “DLGSETSUB”, “DLGMODAL, DLGMODALWITHPARENT”, “DLGMEMODELESS”

**Example**
```
use IFLOGM
include 'resource.fd'
type (dialog) dlg
```
integer         callbacktype
integer         cref
integer         iret

if (callbacktype == dlg_init) then
  ! Change the color of the Progress bar to red
  ! NOTE: The following message succeeds only if Internet Explorer 4.0
  ! or later is installed
  cref = Z'FF'    ! Red
  iret = DlgSendCtrlMessage(dlg, IDC_PROGRESS1, PBM_SETBARCOLOR, 0, cref)
endif

DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR

Dialog Functions: Set the values of dialog control variables. These functions are only available
on Windows* systems.
Module: USE IFLOGM
Syntax
  result = DLGSET (dlg, controlid, value [, index])
  result = DLGSETINT (dlg, controlid, value [, index])
  result = DLGSETLOG (dlg, controlid, value [, index])
  result = DLGSETCHAR (dlg, controlid, value [, index])

  dlg
  (Input) Derived type dialog. Contains dialog box parameters. The components of the type
dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed
by the user.

  controlid
  (Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the
symbolic name for the control or the identifier number, both listed in the Include file (with
extension .FD).

  value
  (Input) Integer, logical, or character. The value of the control’s variable.

  index
  (Input; optional) Integer. Specifies the control variable whose value is set. Necessary if the control
has more than one variable of the same data type and you do not want to set the value of the
default for that type.
Results:

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGSET functions to set the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variables associated with it, but not necessarily all. The control variables are listed in the table in "Control Indexes" in Building Applications. The types of controls they are associated with are listed in the table in "Available Indexes for Each Dialog Control" in Building Applications.

You can use DLGSET to set any control variable. You can also use DLGSETINT to set an integer variable, or DLGSETLOG and DLGSETCHAR to set logical and character values, respectively. If you use DLGSET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to set a variable type that is not available, the DLGSET functions return .FALSE..

Calling DLGSET does not cause a callback routine to be called for the changing value of a control. In particular, when inside a callback, performing a DLGSET on a control does not cause the associated callback for that control to be called. Callbacks are invoked automatically only by user action on the controls in the dialog box. If the callback routine needs to be called, you can call it manually after the DLGSET is executed.

If two or more controls have the same controlid, you cannot use these controls in a DLGSET operation. In this case the function returns .FALSE..

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: "DLGSETSUB", "DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR", "Using Dialog Controls", "Dialog Routines", and "Dialog Controls" in Building Applications

Example

USE IFLOGM
INCLUDE "DLGRADAR.FD"

TYPE (DIALOG)  dlg
LOGICAL        retlog
...
retlog = DLGSET (dlg, IDC_SCROLLBAR1, 400, dlg_range)
retlog = DLGSET (dlg, IDC_CHECKBOX1, .FALSE., dlg_status)
retlog = DLGSET (dlg, IDC_RADIOBUTTON1, "Hot Button", dlg_title)
...
DLGSETCTRLEVENTHANDLER

**Dialog Function:** Assigns user-written event handlers to ActiveX® controls in a dialog box. This function is only available on Windows® systems.

**Module:** USE IFLOGM

**Syntax**
```
result = DLGSETCTRLEVENTHANDLER (dlg, controlid, handler, dispid [, iid])
```

*dlg*  
(Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `DIALOG` are defined with the `PRIVATE` attribute, and cannot be changed or individually accessed by the user.

*controlid*  
(Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file.

*handler*  
(Input) Name of the routine to be called when the event occurs. It must be declared `EXTERNAL`.

*dispid*  
(Input) Integer. Specifies the member id of the method in the event interface that identifies the event.

*iid*  
(Input; optional) Derived type `GUID`, which is defined in the `IFWINTY` module. Specifies the interface identifier of the source (event) interface. If omitted, the default source interface of the ActiveX control is used.

**Results:**

The result type is `INTEGER(4)`. The result is an `HRESULT` describing the status of the operation. When the ActiveX control event occurs, the handler associated with the event is called. You call `DLGSETCTRLEVENTHANDLER` to specify the handler to be called.

The events supported by an ActiveX control and the interfaces of the handlers are determined by the ActiveX control.

You can find this information in one of the following ways:
- By reading the documentation of the ActiveX control.
- By using a tool that lets you examine the type information of the ActiveX control. The OLE-COM Object Viewer in the Intel® Visual Fortran folder is one such tool.
By using the Fortran Module Wizard to generate a module that contains Fortran interfaces to the ActiveX control, and examining the generated module.

The handler that you define in your application must have the interface that the ActiveX control expects, including calling convention and parameter passing mechanisms. Otherwise, your application will likely crash in unexpected ways because of the application’s stack getting corrupted.

Note that an object is always the first parameter in an event handler. This object value is a pointer to the control’s source (event) interface, not the IDispatch pointer of the control. You can use DLGGET with the DLG_IDISPATCH index to retrieve the control’s IDispatch pointer.

For more information, see "Using ActiveX Controls" in Building Applications.

                                      ! interface.

DLGSETRETURN

Dialog Subroutine: Sets the return value for the DLGMODAL function from within a callback subroutine. This subroutine is only available on Windows* systems.

Module: USE IFLOGM

Syntax

CALL DLGSETRETURN (dlg, retval)
dlg

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

retval

(Input) Integer. Specifies the return value for DLGMODAL upon exiting. DLGSETRETURN overrides the default return value with retval. You can set your own value as a means of determining the condition under which the dialog box was closed. The default return value for an error condition is -1, so you should not use -1 as your return value. DLGSETRETURN should be called from within a callback routine, and is generally used with DLGEXIT, which causes the dialog box to be exited from a control callback rather than the user selecting the OK or Cancel button.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: "DLGEXIT", "DLGMODAL, DLGMODALWITHPARENT"

Example

SUBROUTINE SETRETSUB (dlg, button_id, callbacktype)
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) dlg
LOGICAL is_checked, retlog
INTEGER return, button_id, callbacktype
...
retlog = DLGGET(dlg, IDC_CHECKBOX4, is_checked, dlg_state)
IF (is_checked) THEN
   return = 999 ELSE return = -999
END IF
CALL DLGSETRETURN (dlg, return)
CALL DLGEXIT (dlg)
END SUBROUTINE SETRETSUB

DLGSETSUB

Dialog Function: Assigns your own callback subroutines to dialog controls and to the dialog box. This function is only available on Windows® systems.

Module: USE IFLOGM
Syntax

```fortran
result = DLGSETSUB (dlg, controlid, value [, index])
```

`dlg`
(Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the `PRIVATE` attribute, and cannot be changed or individually accessed by the user.

`controlid`
(Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file, or it can be the identifier of the dialog box.

`value`
(Input) `EXTERNAL`. Name of the routine to be called when the callback event occurs.

`index`
(Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

Results:
The result type is `LOGICAL(4)`. The result is `.TRUE.` if successful; otherwise, `.FALSE.`.

When a callback event occurs (for example, when you select a check box), the callback routine associated with that callback event is called. You use `DLGSETSUB` to specify the subroutine to be called. All callback routines should have the following interface:

```fortran
SUBROUTINE callbackname (dlg, controlid, callbacktype)

!DEC$ ATTRIBUTES DEFAULT :: callbackname
```

`callbackname`
Is the name of the callback routine.

`dlg`
Refers to the dialog box and allows the callback to change values of the dialog controls.

`controlid`
Is the name of the control that caused the callback.

`callbacktype`
Indicates what callback is occurring (for example, DLG_CLICKED, DLG_CHANGE, or DLG_DBLCLICK).
The \textit{controlid} and \textit{callbacktype} parameters let you write a single subroutine that can be used with multiple callbacks from more than one control. Typically, you do this for controls comprising a logical group. You can also associate more than one callback routine with the same control, but you must use then use \textit{index} parameter to indicate which callback routine to use.

The \textit{controlid} can also be the identifier of the dialog box. The dialog box supports two \textit{callbacktypes}, DLG_INIT and DLG_SIZECHANGE. The DLG_INIT callback is executed immediately after the dialog box is created with \textit{callbacktype} DLG_INIT, and immediately before the dialog box is destroyed with \textit{callbacktype} DLG_DESTROY. DLG_SIZECHANGE is called when the size of a dialog is changed.

Callback routines for a control are called after the value of the control has been updated based on the user’s action.

If two or more controls have the same \textit{controlid}, you cannot use these controls in a DLGSETSUB operation. In this case, the function returns .FALSE.. For more information, see "Dialog Callback Routines" in \textit{Building Applications}.

\textbf{Compatibility}

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

\textbf{See Also:} "DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR", "DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR"

\textbf{Example}

PROGRAM DLGPROG
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (dialog) mydialog
LOGICAL retlog
INTEGER return
EXTERNAL RADIOSUB
retlog = DLGINIT(IDD_mydlg, dlg)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON1, RADIOSUB)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON2, RADIOSUB)
return = DLGMODAL(dlg)
END

SUBROUTINE RADIOSUB( dlg, id, callbacktype )
!DEC$ ATTRIBUTES DEFAULT :: callbackname
USE IFLOGM
TYPE (dialog) dlg
INTEGER id, callbacktype
INCLUDE 'MYDLG.FD'
CHARACTER(256) text
INTEGER cel, far, retint
LOGICAL retlog
SELECT CASE (id)
  CASE (IDC_RADIO_BUTTON1)
    ! Radio button 1 selected by user so
    ! change text accordingly
    text = 'Statistics Package A'
    retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
  CASE (IDC_RADIO_BUTTON2)
    ! Radio button 2 selected by user so
    ! change text accordingly
    text = 'Statistics Package B'
    retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
END SELECT
END SUBROUTINE RADIOSUB

DLGSETTITLE

Dialog Subroutine: Sets the title of a dialog box. This subroutine is only available on Windows* systems.

Module: USE IFLOGM

Syntax

CALL DLGSETTITLE (dlg, title)

dlg
(Input) Derived type dialog. Contains dialog box parameters. The components of the type
dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed
by the user.

title
(Input) Character*(*). Specifies text to be the title of the dialog box.

Use this routine when you want to specify the title for a dialog box.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “DLGINIT, DLGINITWITHRESOURCEHANDLE”, “DLGMODAL,
DLGMODALWITHPARENT”, “DLGMODELESS”
Example
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGSETTITLE(mydialog, "New Title")
...

DLGUNINIT

Dialog Subroutine: Deallocates memory associated with an initialized dialog. This subroutine is only available on Windows* systems.

Module: USE IFLOGM

Syntax
CALL DLGUNINIT (dlg)

dlg
(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

You should call DLGUNINIT when a dialog that was successfully initialized by DLGINIT is no longer needed. DLGUNINIT should only be called on a dialog initialized with DLGINIT. If it is called on an uninitialized dialog or one that has already been deallocated with DLGUNINIT, the result is undefined.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

TYPE (DIALOG) mydialog
LOGICAL retlog
...
Descriptions of the Library Routines

```
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGUNINIT (mydialog)
END
```

**DRAND, DRANDM**

**Portability Functions:** Return double-precision random numbers in the range 0.0 through 1.0.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{DRAND} \left( \text{iflag} \right) \\
\text{result} = \text{DRANDM} \left( \text{iflag} \right)
\]

**iflag**

(Input) INTEGER(4). Controls the way the random number is selected.

**Results:**

The result type is REAL(8). Return values are:

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, then restarted, and the first random</td>
</tr>
<tr>
<td></td>
<td>value is selected.</td>
</tr>
</tbody>
</table>

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** the RANDOM_NUMBER and RANDOM_SEED intrinsic procedures in the Language Reference

**Example**

```
USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
CALL print_rand
```
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,',',':',num
  END SUBROUTINE
END

DRANSET

Portability Subroutine: Sets the seed for the random number generator.
Module: USE IFPORT
Syntax
  CALL DRANSET (seed)
seed
(Input) REAL(8). The reset value for the seed.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB
See Also: “RANGET”

DTIME

Portability Function: Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.
Module: USE IFPORT
Syntax
  result = DTIME (tarray)
tarray
(Output) REAL(4). A rank one array with two elements:
  • tarray(1) – Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
• `tarray(2)` – Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

**Results:**
The result type is REAL(4). The result is the total CPU time, which is the sum of `tarray(1)` and `tarray(2)`. If an error occurs, –1 is returned.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** the DATE_AND_TIME and CPU_TIME intrinsic procedures in the *Language Reference*

**Example**

```fortran
USE IFPORT
REAL(4) I, TA(2)
I = DTIME(TA)
write(*,*) 'Program has been running for', I, 'seconds.'
write(*,*) 'This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'
```

**ELLIPSE, ELLIPSE_W**

**Graphics Functions:** Draw a circle or an ellipse using the current graphics color. These functions are only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = ELLIPSE (control, x1, y1, x2, y2)
result = ELLIPSE_W (control, wx1, wy1, wx2, wy2)
```

**control**

(Input) INTEGER(2). Fill flag. Can be one of the following symbolic constants:

• `$GFILLINTERIOR` - Fills the figure using the current color and fill mask.
• `$GBORDER` - Does not fill the figure.

**x1, y1**

(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

**x2, y2**

(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
wx1, wy1
(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2
(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

**Results:**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the ellipse is clipped or partially out of bounds, the ellipse is considered successfully drawn, and the return is 1. If the ellipse is drawn completely out of bounds, the return is 0.

The border is drawn in the current color and line style.

When you use ELLIPSE, the center of the ellipse is the center of the bounding rectangle defined by the viewport-coordinate points \((x1, y1)\) and \((x2, y2)\). When you use ELLIPSE_W, the center of the ellipse is the center of the bounding rectangle defined by the window-coordinate points \((wx1, wy1)\) and \((wx2, wy2)\). If the bounding-rectangle arguments define a point or a vertical or horizontal line, no figure is drawn.

The control option given by $GFILLINTERIOR is equivalent to a subsequent call to the FLOODFILLRGB function using the center of the ellipse as the start point and the current color (set by SETCOLORRGB) as the boundary color.

---

**NOTE.** The ELLIPSE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Ellipse routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Ellipse. For more information, see “Special Naming Convention for Certain QuickWin and Win32 Graphics Routines” in Building Applications.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** "FLOODFILLRGB, FLOODFILLRGB_W", "GRSTATUS", "SETCOLORRGB", "SETFILLMASK"

**Example**

This program draws the shape shown below.

```fortran
! compile as QuickWin or Standard Graphics application
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80;  y1 = 50
x2 = 240; y2 = 150
```
ETIME

**Portability Function:** Returns the elapsed CPU time, in seconds, of the process that calls it.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{ETIME} \left( \text{array} \right)
\]

\text{tarray}

(\text{Output}) \text{REAL}(4). Must be a rank one array with two elements:

- \text{array}(1) – Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
- \text{array}(2) – Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

**Results:**

The result type is \text{REAL}(4). The result is the total CPU time, which is the sum of \text{array}(1) and \text{array}(2). If an error occurs, –1 is returned.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** the DATE_AND_TIME and CPU_TIME intrinsic procedures in the Language Reference

**Example**

\begin{verbatim}
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
\end{verbatim}
write(*,*) 'Program has used', I, 'seconds of CPU time.'
write(*,*) '  This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'

FDATE

Portability Function or Subroutine: Returns the current date and time as an ASCII string.
Module: USE IFPORT
Function Syntax:
    result = FDATE ( )
Subroutine Syntax:
    CALL FDATE (string)
string
(Optional; Output) Character*(*) . It is returned as a 24-character string in the form:
    Mon Jan 31 04:37:23 2001
Any value in string before the call is destroyed.
Results:
The result of the function FDATE and the value of string returned by the subroutine FDATE(string) are identical. Newline and NULL are not included in the string.
When you use FDATE as a function, declare it as:
    CHARACTER*24 FDATE
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB
See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference
Example
USE IFPORT
CHARACTER*24 today
!
CALL FDATE(today)
write (*,*) ', Today is ', today
!
write (*,*) ', Today is ', fdate()
**FGETC**

**Portability Function:** Reads the next available character from a file specified by a Fortran unit number.

**Module:** USE IFPORT

**Syntax**

```fortran
result = FGETC (lunit, char)
```

- **lunit**
  (Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.

- **char**
  (Output) CHARACTER*1. Next available character in the file. If `lunit` is connected to a console device, then no characters are returned until the Enter key is pressed.

**Results:**

The result type is INTEGER(4). The result is zero if the read is successful, or –1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:

- EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).

If you use WRITE, READ, or any other Fortran I/O statements with `lunit`, be sure to read "Portability Routines" in *Building Applications*.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** "GETCHARQQ", the READ statement in the *Language Reference*

**Example**

```fortran
USE IFPORT
CHARACTER inchar
INTEGER istatus
istatus = FGETC(5,inchar)
PRINT *, inchar
END
```

---

**FINDFILEQQ**

**Portability Function:** Searches for a specified file in the directories listed in the path contained in the environment variable.

**Module:** USE IFPORT
Syntax

\[ \text{result} = \text{FINDFILEQQ} (\text{filename}, \text{varname}, \text{pathbuf}) \]

\text{filename}
(Input) Character*(*). Name of the file to be found.

\text{varname}
(Input) Character*(*). Name of an environment variable containing the path to be searched.

\text{pathbuf}
(Output) Character*(*). Buffer to receive the full path of the file found.

Results:
The result type is INTEGER(4). The result is the length of the string containing the full path of the
found file returned in \text{pathbuf}, or 0 if no file is found.

Compatibility

\text{CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB}

See Also: “\text{FULLPATHQQ}”, “\text{GETFILEINFOQQ}”, “\text{SPLITPATHQQ}”

Example

\begin{verbatim}
USE IFPORT
CHARACTER(256) pathname
INTEGER(4) pathlen
pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)
WRITE (*,*) pathname
END
\end{verbatim}

\textbf{FLOODFILL, FLOODFILL\_W}

\textbf{Graphics Functions}: Fill an area using the current color index and fill mask. These functions are
only available on Windows* systems.

\textbf{Module}: USE IFQWIN

Syntax

\begin{verbatim}
\text{result} = \text{FLOODFILL} (x, y, bcolor)
\text{result} = \text{FLOODFILL\_W} (wx, wy, bcolor)
\end{verbatim}

\text{x, y}
(Input) INTEGER(2). Viewport coordinates for fill starting point.
**bcolor**

(Input) INTEGER(2). Color index of the boundary color.

**wx, wy**

(Input) REAL(8). Window coordinates for fill starting point.

**Results:**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color bcolor, or if the starting point lies outside the clipping region).

FLOODFILL begins filling at the viewport-coordinate point (x, y). FLOODFILL_W begins filling at the window-coordinate point (wx, wy). The fill color used by FLOODFILL and FLOODFILL_W is set by SETCOLOR. You can obtain the current fill color index by calling GETCOLOR. These functions allow access only to the colors in the palette (256 or less). To access all available colors on a VGA (262,144 colors) or a true color system, use the RGB functions FLOODFILLRGB and FLOODFILLRGB_W.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current graphics color index set by SETCOLOR. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color bcolor.

---

**NOTE.** The FLOODFILL routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the FloodFill routine by including the IFWIN module, you need to specify the routine name as MSFWINS$FloodFill. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** “FLOODFILLRGB, FLOODFILLRGB_W”, “ELLIPSE, ELLIPSE_W”, “GETCOLOR”, “GETFILLMASK”, “GRSTATUS”, “PIE, PIE_W”, “SETCLIPRGN”, “SETCOLOR”, “SETFILLMASK”

**Example**

USE IFQWIN

INTEGER(2) status, bcolor, red, blue

INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
red = 4
blue = 1
status = SETCOLOR(red)
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLOR()
status = SETCOLOR (blue)
xinterior = 160; yinterior = 100
status = FLOODFILL (xinterior, yinterior, bcolor)
END

FLOODFILLRGB, FLOODFILLRGB_W

**Graphics Functions:** Fill an area using the current Red-Green-Blue (RGB) color and fill mask. These functions are only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```
result = FLOODFILLRGB (x, y, color)
result = FLOODFILLRGB_W (wx, wy, color)
```

- **x, y**
  (Input) INTEGER(2). Viewport coordinates for fill starting point.

- **color**
  (Input) INTEGER(4). RGB value of the boundary color.

- **wx, wy**
  (Input) REAL(8). Window coordinates for fill starting point.

**Results:**

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color *color*, or if the starting point lies outside the clipping region).

FLOODFILLRGB begins filling at the viewport-coordinate point (*x, y*). FLOODFILLRGB_W begins filling at the window-coordinate point (*wx, wy*). The fill color used by FLOODFILLRGB and FLOODFILLRGB_W is set by SETCOLORRGB. You can obtain the current fill color by calling GETCOLORRGB.
If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current color set by SETCOLORRGB. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color color.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** “ELLIPSE, ELLIPSE_W”, “FLOODFILL, FLOODFILL_W”, “GETCOLORRGB”, “GETFILLMASK”, “GRSTATUS”, “PIE, PIE_W”, “SETCLIPRGN”, “SETCOLORRGB”, “SETFILLMASK”

**Example**

! Build as a QuickWin or Standard Graphics App.

USE IFQWIN

INTEGER(2) status

INTEGER(4) result, bcolor

INTEGER(2) x1, y1, x2, y2, xinterior, yinterior

x1 = 80; y1 = 50
x2 = 240; y2 = 150
result = SETCOLORRGB(Z'008080') ! red
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLORRGB( )
result = SETCOLORRGB (Z'FF0000') ! blue
xinterior = 160; yinterior = 100
result = FLOODFILLRGB (xinterior, yinterior, bcolor)
END

**FLUSH**

**Portability Subroutine:** Flushes the contents of an external unit buffer into its associated file.

**Module:** USE IFPORT

**Syntax**

CALL FLUSH (lunit)

*lunit*

(Input) INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.
FOCUSQQ

QuickWin Function: Sets focus to the window with the specified unit number. This function is only available on Windows® systems.

Module: USE IFQWIN

Syntax

```
result = FOCUSQQ (iunit)
```

**iunit**

(Input) INTEGER(4). Unit number of the window to which the focus is set. Unit numbers 0, 5, and 6 refer to the default startup window.

Results:

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Units 0, 5, and 6 refer to the default window only if the program does not specifically open them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

Unlike SETACTIVEQQ, FOCUSQQ brings the specified unit to the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```
Descriptions of the Library Routines

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

Compatibility

QUICKWIN GRAPHICS LIB

See Also: "SETACTIVEQQ", "INQFOCUSQQ", "Using QuickWin" in Building Applications

FOR_DESCRIPTOR_ASSIGN

Run-time Subroutine: Creates an array descriptor in memory. This subroutine is only available on Windows* systems.

Module: USE IFCORE

Syntax

CALL FOR_DESCRIPTOR_ASSIGN (dp, base, size, reserved, rank, dims_info)

dp
(Input) A Fortran 95/90 pointer to an array; the array can be of any data type.

base
(Input) INTEGER(4) or INTEGER(8). The base address of the data being described by dp.

size
(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).

reserved
(Input) INTEGER(4). A combination (using bitwise OR) of the following symbolic constants, which are defined in IFCORE.F90:

• FOR_DESCRIPTOR_ARRAY_DEFINED – Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.

• FOR_DESCRIPTOR_ARRAY_NODEALLOC – Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

    integer, pointer :: p(:)
    integer, target :: t
    p => t          ! t cannot be deallocated
    allocate(p(10)) ! t can be deallocated

If the bit is set, the array cannot be deallocated.
• FOR_DESCRIPTOR_ARRAY_CONTIGUOUS – Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

rank
(Input) INTEGER(4). The rank of the array pointed to.

dims_info
(Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```
TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND  !Lower bound for the dimension
  INTEGER(4) UPPERBOUND  !Upper bound for the dimension
  INTEGER(4) STRIDE      !Stride for the dimension
END TYPE FOR_DIMS_INFO
```

The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran 95/90 pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

See Also: the POINTER Attribute and Statement in the Language Reference

Example

```fortran
use IFCORE
common/c_array/ array
real(8) array(5,5)
external  init_array
external  c_print_array
real(8),pointer :: p_array(:,:)
type(FOR_DIMS_INFO) dims_info(2)

  call init_array()

  do i=1,5
    do j=1,5
      print *,i,j, array(i,j)
    end do
  end do

dims_info(1)%LOWERBOUND = 11
dims_info(1)%UPPERBOUND = 15
```
dims_info(1)%STRIDE = 1

 dims_info(2)%LOWERBOUND = -5
 dims_info(2)%UPPERBOUND = -1
 dims_info(2)%STRIDE = 1

call FOR_DESCRIPTOR_ASSIGN(p_array, 
  LOC(array), 
  SIZEOF(array(1,1)), 
  FOR_DESCRIPTOR_ARRAY_DEFINED .or. 
  FOR_DESCRIPTOR_ARRAY_NODEALLOC .or. 
  FOR_DESCRIPTOR_ARRAY_CONTIGUOUS, 
  2, 
  dims_info )

p_array = p_array + 1

call c_print_array()

doend

The following shows the C program containing init_array and c_print_array:

#include <stdio.h>

#if !defined(_WIN32) && !defined(_WIN64)
#define C_ARRAY c_array_
#define INIT_ARRAY init_array_
#define C_PRINT_ARRAY c_print_array_
#endif

double C_ARRAY[5][5];
void INIT_ARRAY(void);
void C_PRINT_ARRAY(void);

void INIT_ARRAY(void)
{
  int i,j;
  for(i=0;i<5;i++)
    for(j=0;j<5;j++)
      C_ARRAY[i][j] = j + 10*i;
}

void C_PRINT_ARRAY(void)
FOR_GET_FPE

Run-time Function: Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.

Module: USE IFCORE

Syntax

result = FOR_GET_FPE ( )

Results:

The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFQWIN module file.

To set floating-point exception flags after program initialization, use "FOR_SET_FPE".

Example

USE IFCORE
INTEGER*4 FPE_FLAGS
FPE_FLAGS = FOR_GET_FPE ( )

for_rtl_finish_

Run-Time Function: Cleans up the Fortran run-time environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

Syntax

result = for_rtl_finish_ ( )
Results:
The result is an I/O status value. For information on these status values, see "Using the IOSTAT Value and Fortran Exit Codes" in Building Applications.

To initialize the Fortran run-time environment, use “for_rtl_init.”

Example
Consider the following C code:

```c
int io_status;
int for_rtl_finish_ ( );
io_status = for_rtl_finish_ ( );
```

**for_rtl_init**

**Run-Time Subroutine:** Initializes the Fortran run-time environment. It establishes handlers and floating-point exception handling, so Fortran subroutines behave the same as when called from a Fortran main program.

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

**Syntax**

```c
CALL for_rtl_init_ (argcount, actarg)
```

*argcount*

Is a command-line parameter describing the argument count.

*actarg*

Is a command-line parameter describing the actual arguments.

To clean up the Fortran run-time environment, use “for_rtl_finish.”

Example
Consider the following C code:

```c
int argc;
char **argv;
void for_rtl_init_ (int *, char **);
for_rtl_init_ (&argc, argv);
```

**FOR_SET_FPE**

**Run-time Function:** Sets the floating-point exception flags. This routine can be called from a C or Fortran program.
Module: USE IFCORE

Syntax

result = FOR_SET_FPE (a)

*a*

Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

Results:

The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file. To get the current settings of the floating-point exception flags, use "FOR_GET_FPE".

Example

USE IFCORE
INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS
OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)

FOR_SET_REENTRANCY

Run-Time Function: Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits. This routine can be called from a C or Fortran program.

Module: USE IFCORE

Syntax

result = FOR_SET_REENTRANCY (mode)

*mode*

Must be of type INTEGER(4) and contain one of the following options:

- **FOR_K_REENTRANCY_NONE**
  
  Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will *not* be reentered due to asynchronous system traps (ASTs) or threads within the application.

- **FOR_K_REENTRANCYASYNCH**
  
  Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.

- **FOR_K_REENTRANCY_THREADED**
  
  Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.
• FOR_K_REENTRANCY_INFO
  Tells the Fortran RTL to return the current reentrancy mode.

  **Results:**
  The result type is INTEGER(4). The return value represents the previous setting of the Fortran
  Run-Time Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in
  which case the return value represents the current setting.

  You must be using an RTL that supports the level of reentrancy you desire. For example,
  FOR_SET_REENTRANCY ignores a request for thread protection
  (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe
  RTL.

  **Example**
  
  ```fortran
  PROGRAM SETREENT
  USE IFCORE
  INTEGER*4 MODE
  CHARACTER*10 REENT_TXT(3) /'NONE    ','ASYNCH  ','THREADED'/
  PRINT*,'Setting Reentrancy mode to ',REENT_TXT(MODE+1)
  MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
  PRINT*,'Previous Reentrancy mode was ',REENT_TXT(MODE+1)
  MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
  PRINT*,'Current Reentrancy mode is ',REENT_TXT(MODE+1)
  END
  ```

  **FPUTC**

  **Portability Function:** Writes a character to the file specified by a Fortran external unit,
  bypassing normal Fortran input/output.

  **Module:** USE IFPORT

  **Syntax**
  
  ```fortran
  result = FPUTC (lunit, char)
  ```

  *lunit*
  (Input) INTEGER(4). Unit number of a file.

  *char*
  (Output) Character*(*) Variable whose value is to be written to the file corresponding to *lunit.*
Results:
The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

EINVAL - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read "Portability Routines" in Building Applications.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: "I/O Formatting" in the Language Reference, "Files, Devices, and I/O" in Building Applications

Example
use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit, file = 'fputc.dat')
do i = 1,26
   char1 = char(123-i)
i4 = fputc(1, char1) ! make valid writes
   if (i4.ne.0) iflag = 1
endo
rewind (1)
read (1,'(a)') string
print *, string

FSEEK

Portability Function: Repositions a file specified by a Fortran external unit.
Module: USE IFPORT
Syntax
   result = FSEEK (lunit, offset, from)
lunit
   (Input) INTEGER(4). External unit number of a file.
offset

(Input) INTEGER(4) or INTEGER(8). Offset in bytes, relative to \textit{from}, that is to be the new location of the file marker.

\textit{from}

(Input) INTEGER(4). A position in the file. It must be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Variable</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SEEK_SET</td>
<td>Positions the file relative to the beginning of the file.</td>
</tr>
<tr>
<td>1</td>
<td>SEEK_CUR</td>
<td>Positions the file relative to the current position.</td>
</tr>
<tr>
<td>2</td>
<td>SEEK_END</td>
<td>Positions the file relative to the end of the file.</td>
</tr>
</tbody>
</table>

Results:

The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:

- \textsc{EINVAL}: The specified unit is invalid (either not already open, or an invalid unit number), or the \textit{from} parameter is invalid.

The file specified in \textit{lunit} must be open.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

Example

```fortran
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1,file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1,offset,ipos)
if (.NOT. stat) then
  istat=fgetc(1,ichar)
  print *, 'data is ',ichar
end if
```

FSTAT

\textbf{Portability Function:} Returns detailed information about a file specified by a external unit number.
Module: USE IFPORT

Syntax

\[
\text{result} = \text{FSTAT} \left( \text{lunit}, \text{statb} \right)
\]

\text{lunit}

(Input) INTEGER(4). External unit number of the file to examine.

\text{statb}

(Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of \text{statb} contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{statb(1)}</td>
<td>Device the file resides on</td>
<td>W{*}32, W{*}64: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L{*}X: System dependent</td>
</tr>
<tr>
<td>\text{statb(2)}</td>
<td>File inode number</td>

<td>L{*}X: System dependent</td>
</tr>
<tr>
<td>\text{statb(11)}</td>
<td>Time of last file status change (^1)</td>
<td>W{*}32, W{*}64: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L{*}X: System dependent</td>
</tr>
<tr>
<td>\text{statb(12)}</td>
<td>Blocksize for file system I/O operations</td>
<td>W{*}32, W{*}64: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L{*}X: System dependent</td>
</tr>
</tbody>
</table>

---

1. Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).
**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINV (lunit is not a valid unit number, or is not open).

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>

</tbody>
</table>
STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the INQUIRE statement in the Language Reference, “STAT”

**Example**

USE IFPORT
integer(4) statarray(12), istat
OPEN (unit=1, file='datfile.dat')
ISTAT = FSTAT (1, statarray)
if (.NOT. istat) then
   print *, statarray
end if

**FTELL, FTELLI8**

Portability Functions: Return the current position of a file.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{FTELL} \left( lunit \right) \\
\text{result} = \text{FTELLI8} \left( lunit \right)
\]

\( lunit \) (Input) INTEGER(4). External unit number of a file.

Results:

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

\[ \text{EINVAL:} \ lunit \ \text{is not a valid unit number, or is not open.} \]

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB
FULLPATHQQ

**Portability Function:** Returns the full path for a specified file or directory.

**Module:** USE IFPORT

**Syntax**

```
result = FULLPATHQQ (name, pathbuf)
```

**name**

(Input) Character*(*). Item for which you want the full path. Can be the name of a file in the current directory, a relative directory or file name, or a network uniform naming convention (UNC) path.

**pathbuf**

(Output) Character*(*). Buffer to receive full path of the item specified in name.

**Results:**

The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails (usually for an invalid name). The length of the full path depends upon how deeply the directories are nested on the drive you are using. If the full path is longer than the character buffer provided to return it (pathbuf), FULLPATHQQ returns only that portion of the path that fits into the buffer.

Check the length of the path before using the string returned in pathbuf. If the longest full path you are likely to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the largest possible path buffer with the following statements:

```
USE IFPORT
 CHARACTER($MAXPATH) pathbuf
```

$MAXPATH is a symbolic constant defined in IFQWIN.F90 as 260.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** "SPLITPATHQQ"

**Example**

```
USE IFPORT
USE IFCORE
 CHARACTER($MAXPATH) buf
 CHARACTER(3) drive
 CHARACTER(256) dir
 CHARACTER(256) name
 CHARACTER(256) ext
```
CHARACTER(256)      file
INTEGER(4)          len

DO WHILE (.TRUE.)
  WRITE (*,*)
  WRITE (*,'(A, ")') ' Enter filename (Hit & RETURN to exit): '

  len = GETSTRQQ(file)
  IF (len .EQ. 0) EXIT
  len = FULLPATHQQ(file, buf)
  IF (len .GT. 0) THEN
    WRITE (*,*) buf(:len)
  ELSE
    WRITE (*,*) 'Can''t get full path'
    EXIT
  END IF

  ! Split path
  WRITE (*,*)
  len = SPLITPATHQQ(buf, drive, dir, name, ext)
  IF (len .NE. 0) THEN
    WRITE (*, 900) ' Drive: ', drive
    WRITE (*, 900) ' Directory: ', dir(1:len)
    WRITE (*, 900) ' Name: ', name
    WRITE (*, 900) ' Extension: ', ext
  ELSE
    WRITE (*, *) 'Can''t split path'
  END IF
END IF
END DO

900  FORMAT (A, A)

GERROR

Run-Time Subroutine: Returns a message for the last error detected by a Fortran run-time routine.

Module: USE IFCORE
Syntax

CALL GERROR (string)

string
(Output) Character*(*). Message corresponding to the last detected error.
The last detected error does not necessarily correspond to the most recent function call. The compiler resets string only when another error occurs.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: “PERROR”, “IERRNO”

Example
USE IFCORE
character*40 errtext
character char1
integer*4 iflag, i4
...Open unit 1 here
i4=fgetc(1,char1) if (i4) then
   iflag = 1
   Call GERROR (errtext)
   print *, errtext
end if

GETACTIVEQQ

QuickWin Function: Returns the unit number of the currently active child window. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = GETACTIVEQQ ( )

Results:
The result type is INTEGER(4). The result is the unit number of the currently active window. If no child window is active, it returns the parameter QWIN$NOACTIVEWINDOW (defined in IFQWIN.F90).

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “SETACTIVEQQ”, “GETHWNDQQ”, "Using QuickWin" in Building Applications
GETARCINFO

**Graphics Function:** Determines the endpoints (in viewport coordinates) of the most recently drawn arc or pie. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
RESULT = GETARCINFO (PSTART, PEND, PPANT)
```

**pstart**
(Output) Derived type `xycoord`. Viewport coordinates of the starting point of the arc.

**pend**
(Output) Derived type `xycoord`. Viewport coordinates of the end point of the arc.

**ppaint**
(Output) Derived type `xycoord`. Viewport coordinates of the point at which the fill begins.

**Results:**
The result type is INTEGER(2). The result is nonzero if successful. The result is zero if neither the ARC nor the PIE function has been successfully called since the last time CLEARSCREEN or SETWINDOWCONFIG was successfully called, or since a new viewport was selected.

GETARCINFO updates the `pstart` and `pend` `xycoord` derived types to contain the endpoints (in viewport coordinates) of the arc drawn by the most recent call to the ARC or PIE functions. The `xycoord` derived type, defined in `IFQWIN.F90`, is:

```
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

The returned value in `ppaint` specifies a point from which a pie can be filled. You can use this to fill a pie in a color different from the border color. After a call to GETARCINFO, change colors using SETCOLORRGB. Use the new color, along with the coordinates in `ppaint`, as arguments for the FLOODFILLRGB function.

**Compatibility**
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** “ARC, ARC_W”, “FLOODFILLRGB, FLOODFILLRGB_W”, “GETCOLORRGB”, “GRSTATUS”, “PIE, PIE_W”, “SETCOLORRGB”

**Example**

```fortran
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
```
TYPE (xycoord) xystart, xyend, xyfillpt
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 80
x4 = 90; y4 = 180
status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
status = GETARCINFO(xystart, xyend, xyfillpt)
END

GETBKCOLOR

Graphics Function: Returns the current background color index for both text and graphics output. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = GETBKCOLOR ( )

Results:
The result type is INTEGER(4). The result is the current background color index.

GETBKCOLOR returns the current background color index for both text and graphics, as set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background index is 0, which is associated with black unless the user remaps the palette with REMAPPALLETTERGB.

NOTE. The GETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWINSGetBkColor. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.
Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also:  "GETBKCOLORRGB", "SETBKCOLOR", "GETCOLOR", "GETTEXTCOLOR", "REMAPALLPALETTERGB", "REMAPPALETTERGB"

Example
USE IFQWIN
INTEGER(4) bcindex
bcindex = GETBKCOLOR()
SETTEXTCOLORRGB and returned with GETTEXTCOLORRGB. The RGB color value of
graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and
FLOODFILLRGB) is set with SETCOLORRGB and returned with GETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB and
SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The
non-RGB color functions (SETBKCOLOR, SETCOLOR, and SETTEXTCOLOR) use color
indexes rather than true color values. If you use color indexes, you are restricted to the colors
available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of
creating 262,144 (256K) colors or more. To access any available color, you need to specify an
explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color
function.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETCOLORRGB", "GETTEXTCOLORRGB", "SETBKCOLORRGB", "GETBKCOLOR"

Example
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) back, fore, oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETCOLORRGB(Z'FF') ! red
! reverse the screen
back = GETBKCOLORRGB()
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)
oldcolor = SETCOLORRGB(back)
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

GETC

Portability Function: Reads the next available character from external unit 5, which is normally
connected to the console.

Module: USE IFPORT
Syntax
result = GETC (char)

char
(Output) Character*(*). The first character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

Results:
The result is of type INTEGER(4). The result is zero if successful, or –1 if an end-of-file was detected.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAHICS WINDOWS LIB

See Also: “GETCHARQQ”, “GETSTROQ”

Example
use IFPORT
character ans, errtxt*40
print *, 'Enter a character: '
ISTAT = GETC (ans)
if (istat) then
call gerror(errtxt)
end if

GETCHARQQ

Run-Time Function: Returns the next keystroke.
Module: USE IFCORE

Syntax
result = GETCHARQQ ( )

Results:
The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character. If the key pressed is a function or direction key, a hex 'Z'00' or 'Z'E0' is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.
If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn’t there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQQ in your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application.

The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQQ.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

! Program to demonstrate GETCHARQQ
USE IFCORE
CHARACTER(1) key / 'A' /
PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)
WRITE (*,*) ' Type a key: (or q to quit)'
! Read keys until ESC or q is pressed
DO WHILE (ICHAR (key) .NE. ESC)
  key = GETCHARQQ()
! Some extended keys have no ASCII representation
  IF (ICHAR(key) .EQ. NOREP) THEN
    key = GETCHARQQ()
    WRITE (*, 900) 'Not ASCII. Char = NA'
    WRITE (*,*)
  ELSE
    WRITE (*,900) 'ASCII. Char = '
    WRITE (*,901) key
END IF
IF (key .EQ. 'q') THEN
  EXIT
END IF
END DO

900   FORMAT (1X, A, 
901   FORMAT (A)
END

GETCOLOR

Graphics Function: Returns the current graphics color index. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = GETCOLOR()

Results:
The result type is INTEGER(2). The result is the current color index, if successful; otherwise, –1.

GETCOLOR returns the current color index used for graphics over the background color as set with SETCOLOR. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETCOLORRGB”, “GETBKCOLOR”, “GETTEXTCOLOR”, “SETCOLOR”

Example

!  Program to demonstrate GETCOLOR
PROGRAM COLORS
USE IFQWIN
INTEGER(2) loop, loop1, status, color
LOGICAL(4) winstat
REAL rnd1, rnd2, xnum, ynum
type (windowconfig) wc
status = SETCOLOR(INT2(0))
! Color random pixels with 15 different colors
DO loop1 = 1, 15
  color = INT2(MOD(GETCOLOR() + 1, 16))
  status = SETCOLOR (color) ! Set to next color
  DO loop = 1, 75
    ! Set color of random spot, normalized to be on screen
    CALL RANDOM(rnd1)
    CALL RANDOM(rnd2)
    winstat = GETWINDOWCONFIG(wc)
    xnum = wc%numxpixels
    ynum = wc%numypixels
    status = &
    SETPIXEL(INT2(rnd1*xnum + 1), INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum), INT2(rnd2*ynum + 1))
    status = &
    SETPIXEL(INT2(rnd1*xnum - 1), INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum), INT2(rnd2*ynum - 1))
  END DO
END DO
END

GETCOLORRGB

Graphics Function: Returns the current graphics color Red-Green-Blue (RGB) value (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB). This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax
  result = GETCOLORRGB ( )

Results:
The result type is INTEGER(4). The result is the RGB value of the current graphics color.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB) 24 23 16 15 8 7 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O B B B B B B G G G G G G G G R R R R R R</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETCOLORRGB returns the RGB color value of graphics over the background color (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB), set with SETCOLORRGB. GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB.

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETBKCOLORRGB”, “GETTEXTCOLORRGB”, “SETCOLORRGB”, “GETCOLOR”

**Example**

! Build as a QuickWin or Standard Graphics App.

USE IFQWIN

INTEGER(2) numfonts
INTEGER(4) fore, oldcolor

numfonts = INITIALIZEFONTS ( )
oldcolor = SETCOLORRGB(Z'FF')  ! set graphics
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore) ! set background
     ! to graphics color
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB (Z'FF0000') ! set graphics
     ! color to blue
CALL OUTGTEXT("hello, world")
END

GETCONTROLFPQQ

Portability Subroutine: Returns the floating-point processor control word.

Module: USE IFPORT

Syntax

CALL GETCONTROLFPQQ (controlword)

controlword
(Output) INTEGER(2). Floating-point processor control word.

The floating-point control word is a bit flag that controls various modes of the floating-point coprocessor.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z'1000'</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z'1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z'0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z'0300'</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z'0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z'0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z'0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z'0C00'</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z'0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z'0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z'0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z'0000'</td>
<td>Round to nearest</td>
</tr>
</tbody>
</table>
The defaults for the floating-point control word are 53-bit precision, round to nearest, and the
denormal, underflow and inexact precision exceptions disabled. An exception is disabled if its
control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be
disabled by setting the control bits to 1 with SETCONTROLFPQQ.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point
processes generate an appropriate special value (NaN or signed infinity), but the program
continues.

You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on
floating-point exceptions are enabled (by clearing the control bits to 0 with
SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs.
By default, these interrupts cause run-time errors, but you can capture the interrupts with
SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and
SETCONTROLFPQQ to change the control word. Most users do not need to change the default
settings. For a full discussion of the floating-point control word, exceptions, and error handling,
see "The Floating-Point Environment" in *Building Applications*.

<td>Z'0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>
! rounding
control = IOR(control, FPCW$DOWN)         ! set to
! round down

CALL SETCONTROLFPQQ(control)
END IF
END

GETCURRENTPOSITION, GETCURRENTPOSITION_W

Graphics Subroutines: Return the coordinates of the current graphics position. These subroutines are only available on Windows* systems.

Module: USE IFQWIN

Syntax
CALL GETCURRENTPOSITION (t)
CALL GETCURRENTPOSITION_W (wt)

t  
(Output) Derived type xycoord. Viewport coordinates of current graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:
TYPE xycoord
  INTEGER(2) xcoord   ! x-coordinate
  INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord

wt  
(Output) Derived type wxycoord. Window coordinates of current graphics position. The derived type wxycoord is defined in IFQWIN.F90 as follows:
TYPE wxycoord
  REAL(8) wx    ! x-coordinate
  REAL(8) wy    ! y-coordinate
END TYPE wxycoord

LINETO, MOVETO, and OUTGTEXT all change the current graphics position. It is in the center of the screen when a window is created.

Graphics output starts at the current graphics position returned by GETCURRENTPOSITION or GETCURRENTPOSITION_W. This position is not related to normal text output (from OUTTEXT or WRITE, for example), which begins at the current text position (see SETTEXTPOSITION). It does, however, affect graphics text output from OUTGTEXT.
Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “LINETO, LINETO_W”, “MOVETO, MOVETO_W”, “OUTGTEXT”, “SETTEXTPOSITION”, “GETTEXTPOSITION”

Example

! Program to demonstrate GETCURRENTPOSITION
USE IFQWIN
TYPE (xycoord) position
INTEGER(2)     result
result = LINETO(INT2(300), INT2(200))
CALL GETCURRENTPOSITION( position )
IF (position%xcoord .GT. 50) THEN
   CALL MOVETO(INT2(50), position%ycoord, position)
   WRITE(*,*) "Text unaffected by graphics position"
END IF
result = LINETO(INT2(300), INT2(200))
END

GETCWD

Portability Function: Returns the path of the current working directory.
Module: USE IFPORT
Syntax

   result = GETCWD (dirname)

dirname
(Output) Character *(*) . Name of the current working directory path, including drive letter.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “GETDRIVEDIRQQ”
Example

   use ifport
   character*30 dirname
!   variable dirname must be long enough to hold entire string
Descriptions of the Library Routines

integer(4) istat
ISTAT = GETCWD (dirname)
IF (ISTAT == 0) write *, 'Current directory is ',dirname

GETDAT

Portability Subroutine: Returns the date.
Module: USE IFPORT
Syntax
   CALL GETDAT (iyr, imon, iday)

iyr
(Output) INTEGER(4) or INTEGER(2). Year (xxxx AD).
imon
(Output) INTEGER(4) or INTEGER(2). Month (1-12).
iday
(Output) INTEGER(4) or INTEGER(2). Day of the month (1-31).

This subroutine is thread-safe.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

See Also: “GETTIM”, “SETDAT”, “SETTIM”, “FDATE”, “IDATE4”, “JDATE”

Example
! Program to demonstrate GETDAT and GETTIM
USE IFPORT
INTEGER(4) tmpday, tmpmonth, tmpyear
INTEGER(4) tmphour, tmpminute, tmpsecond, tmphund
CHARACTER(1) mer

CALL GETDAT(tmpyear, tmpmonth, tmpday)
CALL GETTIM(tmphour, tmpminute, tmpsecond, tmphund)
IF (tmphour .GT. 12) THEN
   mer = 'p'
   tmphour = tmphour - 12
ELSE
   mer = 'a'
END IF
WRITE (*, 900) tmpmonth, tmpday, tmpyear
900  FORMAT(I2, '/', I2.2, '/', I4.4)
WRITE (*, 901) tmphour, tmpminute, tmppsecond, tmphund, mer
901  FORMAT(I2, ':', I2.2, ':', I2.2, ':', I2.2, ' ', &
A, 'm')
END

GETDRIVEDIRQQ

Portability Function: Returns the path of the current working directory on a specified drive.

Module: USE IFPORT

Syntax

result = GETDRIVEDIRQQ (drivedir)

drivedir
(Input; output) Character*(*) . On input, drive whose current working directory path is to be
returned. On output, string containing the current directory on that drive in the form d:\dir.

Results:

The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory
on the specified drive. Zero is returned if the path is longer than the size of the character buffer
drivedir.

You specify the drive from which to return the current working directory by putting the drive letter
into drivedir before calling GETDRIVEDIRQQ. To make sure you get information about the
current drive, put the symbolic constant FILE$CURDRIVE (defined in IFPORT.F90) into
drivedir.

Because drives are identified by a single alphabetic character, GETDRIVEDIRQQ examines only
the first letter of drivedir. For instance, if drivedir contains the path c:\fps90\bin,
GETDRIVEDIRQQ (drivedir) returns the current working directory on drive C and disregards the
rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive
specified in drivedir. If the full path is longer than the length of drivedir, GETDRIVEDIRQQ
returns only the portion of the path that fits into drivedir. If you are likely to encounter a long path,
allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* and Mac OS* systems, the function gets a path only when symbolic constant
FILE$CURDRIVE has been applied to drivedir.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
See Also: “CHANGEDRIVEQQ”, “CHANGEDIRQQ”, “GETDRIVESIZEQQ”, “GETDRIVESQQ”, “GETLASTERRORQQ”, “SPLITPATHQQ”

Example

! Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
! Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length .GT. 0) THEN
   WRITE (*,*) 'Current directory is: '
   WRITE (*,*) dir
ELSE
   WRITE (*,*) 'Failed to get current directory'
END IF
END

GETDRIVESIZEQQ

Portability Function: Returns the total size of the specified drive and space available on it.

Module: USE IFPORT

Syntax

   result = GETDRIVESIZEQQ (drive, total, avail)

   drive
      (Input) Character*(*) String containing the letter of the drive to get information about.

   total
      (Output) INTEGER(4) or INTEGER(4),DIMENSION(2) or INTEGER(8). Total number of bytes on the drive.

   avail
      (Output) INTEGER(4) or INTEGER(4),DIMENSION(2) or INTEGER(8). Number of bytes of available space on the drive.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
The data types and dimension (if any) specified for the `total` and `avail` arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of `drive`. The drive letter can be uppercase or lowercase. You can use the constant $\text{FILE\$CURDRIVE}$ (defined in `IFPORT.F90`) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “GETLASTERRORQQ”, “GETDRIVESQQ”, “GETDRIVEDIRQQ”, “CHANGEDRIVEQQ”, “CHANGEDIRQQ”

**Example**

```fortran
! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A, A)') ' Drives available: ', drives
!
! Cycle through them for free space and write to console
DO i = 1, 26
  adrive = drives(i:i)
  status = .FALSE.
  WRITE (*,'(A, A, A, \)') ' Drive ', CHAR(i + 64), ',:'
  IF (adrive .NE. ' ') THEN
    status = GETDRIVESIZEQQ(adrive, total, avail)
  END IF
  IF (status) THEN
    WRITE (*,*) avail, ' of ', total, ' bytes free.'
  ELSE
```
WRITE (*,*) 'Not available'
END IF
END DO
END

GETDRIVESQQ

Portability Function: Reports which drives are available to the system.
Module: USE IFPORT
Syntax
result = GETDRIVESQQ ( )
Results:
The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.
The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A  CD     ' is returned.
On Linux* and Mac OS* systems, the function returns a string filled with spaces.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
See Also: “GETDRIVEDIRQQ”, “GETDRIVESIZEQQ”, “CHANGEDRIVEQQ”
Example
See the example for “GETDRIVESIZEQQ”.

GETENV

Portability Subroutine: Returns the value of an environment variable.
Module: USE IFPORT
Syntax
CALL GETENV (ename, evalue)
ename
(Input) Character*(*) . Environment variable to search for.
evalue
(Output) Character*(*) . Value found for ename. Blank if ename is not found.
GETENVQQ

Portability Function: Returns the value of an environment variable.

Module: USE IFPORT

Syntax
   result = GETENVQQ (varname, value)

varname
(Input) Character*(*) . Name of environment variable.

value
(Output) Character*(*) . Value of the specified environment variable, in uppercase.

Results:
The result type is INTEGER(4). The result is the length of the string returned in value. Zero is returned if the given variable is not defined.

GETENVQQ searches the list of environment variables for an entry corresponding to varname.
Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQQ uses the C runtime routine getenv and SETENVQQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system’s environment.
Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQQ.

GETENVQQ and SETENVQQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

See Also: “SETENVQQ”, “GETLASTERRORQQ”

Example

! Program to demonstrate GETENVQQ and SETENVQQ
USE IFPORT
USE IFCORE
INTEGER(4) lenv, lval
CHARACTER(80) env, val, enval
WRITE (*,900) ' Enter environment variable name to create, & modify, or delete: '

lenv = GETSTRQQ(env)
IF (lenv .EQ. 0) STOP
WRITE (*,900) ' Value of variable (ENTER to delete): '
lval = GETSTRQQ(val)
IF (lval .EQ. 0) val = ' '
enval = env(1:lenv) // '=' // val(1:lval)
IF (SETENVQQ(enval)) THEN
  lval = GETENVQQ(env(1:lenv), val)
  IF (lval .EQ. 0) THEN
    WRITE (*,*) 'Can''t get environment variable'
    ELSE IF (lval .GT. LEN(val)) THEN
      WRITE (*,*) 'Buffer too small'
    ELSE
      WRITE (*,*) env(:lenv), ': ', val(:lval)
      WRITE (*,*) 'Length: ', lval
    END IF
  ELSE
    WRITE (*,*) 'Can''t set environment variable'
  END IF
END IF
ELSE
  WRITE (*,*) 'Can''t get environment variable'
END IF
900  FORMAT (A, 
END
GETEXCEPTIONPTRSQQ (i32, i32em)

Run-Time Function: Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine. This function is only available on Windows* systems.

Module: USE IFCORE

Syntax
result = GETEXCEPTIONPTRSQQ ( )

Results:
The result type is INTEGER(4) on IA-32 processors; INTEGER(8) on Intel EM64T processors. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the EPTR argument to routine TRACERACKQ to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling GETEXCEPTIONPTRSQQ is only valid within a user-defined handler that was established with SIGNALQQ or a direct call to the C rtl signal( ) function.

For a full description of exceptions and error handling, see "The Floating-Point Environment" in Building Applications.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

See Also: TRACERACKQ, GETSTATUSFPQQ, CLEARSTATUSFPQQ, SETCONTROLFPQQ, GETCONTROLFPQQ, SIGNALQQ

Example

PROGRAM SIGTEST
USE IFCORE
... 
R3 = 0.0E0 
STS = SIGNALQQ(MY_HANDLER) 
! Cause a divide by zero exception 
R1 = 3.0E0/R3  
...  
END

INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM) 
USE IFCORE 
... 
EPTRS = GETEXCEPTIONPTRSQQ ()
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)

MY_HANDLER = 1
END

A complete working example can be found in the online samples.

GETEXITQQ

**QuickWin Function:** Returns the setting for a QuickWin application’s exit behavior. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```plaintext
result = GETEXITQQ()
```

**Results:**

The result type is INTEGER(4). The result is exit mode with one of the following constants (defined in IFQWIN.F90):

- **QWIN$EXITPROMPT** - Displays a message box that reads "Program exited with exit status \( n \). Exit Window?", where \( n \) is the exit status from the program.
  
  If you choose Yes, the application closes the window and terminates. If you choose No, the dialog box disappears and you can manipulate the window as usual. You must then close the window manually.

- **QWIN$EXITNOPERSIST** - Terminates the application without displaying a message box.
- **QWIN$EXITPERSIST** - Leaves the application open without displaying a message box.

The default for both QuickWin and Console Graphics applications is QWIN$EXITPROMPT.

**Compatibility**

STANDARD GRAPHICS QUICKWIN.EXE LIB

**See Also:** “SETEXITQQ”, "Using QuickWin" in Building Applications

**Example**

```plaintext
! Program to demonstrate GETEXITQQ
USE IFQWIN
INTEGER i
i = GETEXITQQ()
SELECT CASE (i)
    CASE (QWIN$EXITPROMPT)
```
WRITE(*, *) "Prompt on exit."
CASE (QWIN$EXITNOPERSIST)
  WRITE(*,*) "Exit and close."
CASE (QWIN$EXITPERSIST)
  WRITE(*,*) "Exit and leave open."
END SELECT
END

GETFILEINFOQQ

**Portability Function:** Returns information about the specified file. File names can contain wildcards (* and ?).

**Module:** USE IFPORT

**Syntax**

```fortran
result = GETFILEINFOQQ (files, buffer, handle)
```

**files**
(Input) Character*(*)). Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).

**buffer**
(Output) Derived type FILE$INFO or derived type FILE$INFOI8. Information about a file that matches the search criteria in `files`. The derived type FILE$INFO is defined in IFPORT.F90 as follows:

```fortran
TYPE FILE$INFO
  INTEGER(4) CREATION           ! CREATION TIME (-1 ON FAT)
  INTEGER(4) LASTWRITE          ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS         ! LAST ACCESS (-1 ON FAT)
  INTEGER(4) LENGTH             ! LENGTH OF FILE
  INTEGER(4) PERMIT             ! FILE ACCESS MODE
  CHARACTER(255) NAME           ! FILE NAME
END TYPE FILE$INFO
```

The derived type FILE$INFOI8 is defined in IFPORT.F90 as follows:

```fortran
TYPE FILE$INFOI8
  INTEGER(4) CREATION           ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE          ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS         ! LAST ACCESS (-1 ON FAT)
  INTEGER(8) LENGTH             ! LENGTH OF FILE
END TYPE FILE$INFOI8
```
INTEGER(4) PERMIT ! FILE ACCESS MODE
CHARACTER(255) NAME ! FILE NAME
END TYPE FILE$INFO

handle

(Input; output) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium processors and Intel EM64T processors. Control mechanism. One of the following constants, defined in IFPORT.F90:

• FILE$FIRST – First matching file found.
• FILE$LAST – Previous file was the last valid file.
• FILE$ERROR – No matching file found.

Results:
The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.

The derived-type element variables FILEINFO%CREATION, FILEINFO%LASTWRITE, and FILEINFO%LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively. To break the time and date into component parts, call UNPACKTIMEQQ. FILEINFO%LENGTH contains the length of the file in bytes. FILEINFO%PERMIT contains a set of bit flags describing access information about the file as follows:

<table>
<thead>
<tr>
<th>Bit flag</th>
<th>Access information for the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE$ARCHIVE</td>
<td>Marked as having been copied to a backup device.</td>
</tr>
<tr>
<td>FILE$DIR</td>
<td>A subdirectory of the current directory. Each MS-DOS* directory contains two special files, &quot;.&quot; and &quot;.&quot;: These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory’s parent directory.</td>
</tr>
<tr>
<td>FILE$HIDDEN</td>
<td>Hidden. It does not appear in the directory list you request from the command line, the Microsoft* visual development environment browser, or File Manager.</td>
</tr>
<tr>
<td>FILE$READONLY</td>
<td>Write-protected. You can read the file, but you cannot make changes to it.</td>
</tr>
</tbody>
</table>
You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILEINFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILEINFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERRORQQ to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

END DO
END SUBROUTINE

GETFILLMASK

Graphics Subroutine: Returns the current pattern used to fill shapes. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

    CALL GETFILLMASK (mask)

mask

(Output) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in \textit{mask}, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of \textit{mask} becomes the top 8 bits of the pattern, and the eighth element (byte) of \textit{mask} becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of 0 are unchanged. The current graphics color is set with \texttt{SETCOLORRGB} or \texttt{SETCOLOR}. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with \texttt{SETFILLMASK}), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (\texttt{FLOODFILLRGB}, \texttt{PIE}, \texttt{ELLIPSE}, \texttt{POLYGON}, and \texttt{RECTANGLE}).

\textbf{Compatibility}

\texttt{STANDARD GRAPHICS QUICKWIN GRAPHICS LIB}

\textbf{See Also:} \texttt{"ELLIPSE, ELLIPSE_W", "FLOODFILLRGB, FLOODFILLRGB_W", "PIE, PIE_W", "POLYGON, POLYGON_W", "RECTANGLE, RECTANGLE_W", "SETFILLMASK"}

\textbf{Example}

\begin{verbatim}
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1) style(8). array(8)
INTEGER(2) i
style = 0
style(1) = Z'F'
style(3) = Z'F'
style(5) = Z'F'
style(7) = Z'F'
CALL SETFILLMASK (style)
...
CALL GETFILLMASK (array)
WRITE (*, *) 'Fill mask in bits: '
DO i = 1, 8
  WRITE (*, '('B8')') array(i)
END DO
END
\end{verbatim}
**GETFONTINFO**

**Graphics Function:** Returns the current font characteristics. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETFONTINFO} \left( \text{font} \right)
\]

**font**

(Output) Derived type FONTINFO. Set of characteristics of the current font. The FONTINFO derived type is defined in IFQWIN.F90 as follows:

```
TYPE FONTINFO
  INTEGER(4) type           ! 1 = truetype, 0 = bit map
  INTEGER(4) ascent         ! Pixel distance from top to
  !   baseline
  INTEGER(4) pixwidth       ! Character width in pixels,
  !   0=proportional
  INTEGER(4) pixheight      ! Character height in pixels
  INTEGER(4) avgwidth       ! Average character width in
  !   pixels
  CHARACTER(81) filename    ! File name including path
  CHARACTER(32) facename    ! Font name
  LOGICAL(1) italic         ! .TRUE. if current font
  !   formatted italic
  LOGICAL(1) emphasized     ! .TRUE. if current font
  !   formatted bold
  LOGICAL(1) underline      ! .TRUE. if current font
  !   formatted underlined
END TYPE FONTINFO
```

**Results:**

The result type is INTEGER(2). The result is zero if successful; otherwise, –1.

You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETFONTINFO.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB
See Also: “GETGTEXTEXTENT”, “GETGTEXTROTATION”, “GRSTATUS”, “OUTGTEXT”, “INITIALIZEFONTS”, “SETFONT”.”Using Fonts from the Graphics Library” in Building Applications

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN

TYPE (FONTINFO) info
INTEGER(2)      numfonts, return, line_spacing
numfonts = INITIALIZEFONTS ( )
return = GETFONTINFO(info)
line_spacing = info%pixheight + 2
END

GETGID

Portability Function: Returns the group ID of the user of a process.

Module: USE IFPORT

Syntax

result = GETGID ( )

Results:

The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity the program is running. The result is returned as follows:

• On Windows® systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts. Note that on Windows systems, domain accounts and local accounts can overlap.

• On Linux® and Mac OS® systems, this function returns the group identity for the current process.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL  LIB

Example

USE IFPORT

ISTAT = GETGID( )
GETGTEXTEXTENT

**Graphics Function:** Returns the width in pixels that would be required to print a given string of text (including any trailing blanks) with OUTGTEXT using the current font. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETGTEXTEXTENT} \left( \text{text} \right)
\]

**text**

(Input) Character*(*) Text to be analyzed.

**Results:**

The result type is INTEGER(2). The result is the width of text in pixels if successful; otherwise, –1 (for example, if fonts have not been initialized with INITIALIZEFONTS).

This function is useful for determining the size of text that uses proportionally spaced fonts. You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETGTEXTEXTENT.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** "GETFONTINFO", "OUTGTEXT", "SETFONT", "INITIALIZEFONTS", "GETGTEXTROTATION"

**Example**

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status, pwidth
CHARACTER(80) text
status = INITIALIZEFONTS()
status = SETFONT('t''Arial''h22w10')
pwidth = GETGTEXTEXTENT('How many pixels wide is this?')
WRITE(*,*) pwidth
END
```

GETGTEXTROTATION

**Graphics Function:** Returns the current orientation of the font text output by OUTGTEXT. This function is only available on Windows® systems.

**Module:** USE IFQWIN
Syntax

result = GETGTEXTROTATION ( )

Results:
The result is of type INTEGER(4). It is the current orientation of the font text output in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 tenths of degrees (90°) is straight up, 1800 tenths of degrees (180°) is upside-down and left, 2700 tenths of degrees (270°) is straight down, and so forth.
The orientation for text output with OUTGTEXT is set with SETGTEXTROTATION.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “OUTGTEXT”, “SETFONT”, “SETGTEXTROTATION”

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER ang
REAL rang
ang = GETGTEXTROTATION( )
rang = FLOAT(ang)/10.0
WRITE(*,*) "Text tilt in degrees is: ", rang

GETHWNDQQ

QuickWin Function: Converts a window unit number into a Windows® handle. This function is only available on Windows systems.

Module: USE IFQWIN

Syntax

result = GETHWNDQQ (unit)

unit

(Input) INTEGER(4). The window unit number. If unit is set to QWIN$FRAMEWINDOW (defined in IFQWIN.F90), the handle of the frame window is returned.

Results:
The result type is INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium processors and Intel EM64T processors. The result is a true Windows handle to the window. If unit is not open, it returns –1.
Compatibility

QUICKWIN GRAPHICS LIB

See Also: “GETACTIVEQQ”, “GETUNITQQ”, “SETACTIVEQQ”, “Using QuickWin” in Building Applications

GETIMAGE, GETIMAGE_W

Graphics Subroutines: Store the screen image defined by a specified bounding rectangle. These subroutines are only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL GETIMAGE (x1, y1, x2, y2, image)
CALL GETIMAGE_W (wx1, wy1, wx2, wy2, image)

x1, y1
(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
x2, y2
(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
wx1, wy1
(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2
(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
image
(Output) INTEGER(1). Array of single-byte integers. Stored image buffer.

GETIMAGE defines the bounding rectangle in viewport-coordinate points (x1, y1) and (x2, y2).
GETIMAGE_W defines the bounding rectangle in window-coordinate points (wx1, wy1) and (wx2, wy2).

The buffer used to store the image must be large enough to hold it. You can determine the image size by calling IMAGESIZE at run time, or by using the formula described under IMAGESIZE. After you have determined the image size, you can dimension the buffer accordingly.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “IMAGESIZE, IMAGESIZE_W”, “PUTIMAGE, PUTIMAGE_W”

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1), ALLOCATABLE:: buffer (:)
INTEGER(2) status, x, y, error
INTEGER(4) imsize
x = 50
y = 30
status = ELLIPSE ($GFILLINTERIOR, INT2(x-15), &
          INT2(y-15), INT2(x+15), INT2(y+15))
imsize = IMAGESIZE (INT2(x-16), INT2(y-16), &
          INT2(x+16), INT2(y+16))
ALLOCATE(buffer (imsize), STAT = error)
IF (error .NE. 0) THEN
  STOP 'ERROR: Insufficient memory'
END IF
CALL GETIMAGE (INT2(x-16), INT2(y-16), &
               INT2(x+16), INT2(y+16), buffer)
END

GETLASTERROR

Portability Function: Returns the last error set.
Module: USE IFPORT
Syntax
  result = GETLASTERROR ( )
Results:
The result type is INTEGER(4). The result is the integer corresponding to the last run-time error value that was set.
For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining errno. Your application can then take appropriate action based upon the error number.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
**GETLASTERRORQQ**

**Portability Function:** Returns the last error set by a run-time procedure.

**Module:** USE IFPORT

**Syntax**

```plaintext
result = GETLASTERRORQQ()
```

**Results:**

The result type is INTEGER(4). The result is the most recent error code generated by a run-time procedure.

Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERRORQ retrieves the most recent error message. The error constants are in IFPORT.F90. The following table shows some library routines and the errors each routine produces:

<table>
<thead>
<tr>
<th>Library routine</th>
<th>Errors produced</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>no error</td>

</tbody>
</table>
GETLINESTYLE

**Graphics Function:** Returns the current graphics line style. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = GETLINESTYLE ( )
```

**Results:**

The result type is INTEGER(2). The result is the current line style.

GETLINESTYLE retrieves the mask (line style) used for line drawing. The mask is a 16-bit number, where each bit represents a pixel in the line being drawn.

If a bit is 1, the corresponding pixel is colored according to the current graphics color and logical write mode; if a bit is 0, the corresponding pixel is left unchanged. The mask is repeated for the entire length of the line. The default mask is Z'FFFF' (a solid line). A dashed line can be represented by Z'FF00' (long dashes) or Z'F0F0' (short dashes).

The line style is set with SETLINESTYLE. The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

The line style retrieved by GETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE or PIE.
Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: "LINETO, LINETO_W", "POLYGON, POLYGON_W", "RECTANGLE, RECTANGLE_W", "SETCOLORRGB", "SETFILLMASK", "SETLINESTYLE", "SETWRITEMODE"

Example
! Build as Graphics
USE IFQWIN
INTEGER(2) lstyle
lstyle = GETLINESTYLE()
WRITE (*, 100) lstyle, lstyle
100 FORMAT (1X, ’Line mask in Hex ’, Z4, ’ and binary ’, B16)
END

GETLOG

Portability Subroutine: Returns the user’s login name.
Module: USE IFPORT
Syntax
   CALL GETLOG (name)
name
   (Output) Character*(*) User’s login name.
The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it is truncated. The actual parameter corresponding to name should be long enough to hold the login name. If the supplied actual parameter is too short to hold the login name, the login name is truncated.
If the login name is shorter than the actual parameter corresponding to name, the login name is padded with blanks at the end, until it reaches the length of the actual parameter.
If the login name cannot be determined, all blanks are returned.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
   use IFPORT
   character*20 username
   CALL GETLOG (username)
print *, "You logged in as ", username

GETPHYSCOORD

Graphics Subroutine: Translates viewport coordinates to physical coordinates. This subroutine is only available on Windows® systems.

Module: USE IFQWIN

Syntax

CALL GETPHYSCOORD (x, y, t)

x, y  
(Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.

 t  
(Output) Derived type xycoord. Physical coordinates of the input viewport position. The xycoord derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
    INTEGER(2) xcoord   ! x-coordinate
    INTEGER(2) ycoord   ! y-coordinate
END TYPE xycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area. For a more complete discussion of coordinate systems, see "Understanding Coordinate Systems" in Building Applications.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETVIEWCOORD, GETVIEWCOORD_W", "GETWINDOWCOORD", "SETCLIPRGN", "SETVIEWPORT"

Example

```fortran
! Program to demonstrate GETPHYSCOORD, GETVIEWCOORD, 
! and GETWINDOWCOORD. Build as QuickWin or Standard
! Graphics
USE IFQWIN
TYPE (xycoord)  viewxy, physxy
TYPE (wxycoord) windxy
CALL SETVIEWPORT(INT2(80), INT2(50), &
```
INT2(240), INT2(150))
! Get viewport equivalent of point (100, 90)
CALL GETVIEWCOORD (INT2(100), INT2(90), viewxy)
! Get physical equivalent of viewport coordinates
CALL GETPHYSCOORD (viewxy%xcoord, viewxy%ycoord, &
physxy)
! Get physical equivalent of viewport coordinates
CALL GETWINDOWCOORD (viewxy%xcoord, viewxy%ycoord, &
windxy)
! Write viewport coordinates
WRITE (*,*) viewxy%xcoord, viewxy%ycoord
! Write physical coordinates
WRITE (*,*) physxy%xcoord, physxy%ycoord
! Write window coordinates
WRITE (*,*) windxy%wx, windxy%wy
END

GETPID

**Portability Function:** Returns the process ID of the current process.

**Module:** USE IFPORT

**Syntax**

```plaintext
result = GETPID ( )
```

**Results:**

The result type is INTEGER(4). The result is the process ID number of the current process.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```plaintext
USE IFPORT
INTEGER(4) istat
istat = GETPID()
```

GETPIXEL, GETPIXEL_W

**Graphics Functions:** Return the color index of the pixel at a specified location. These functions are only available on Windows* systems.
Module: USE IFQWIN

Syntax
result = GETPIXEL (x, y)
result = GETPIXEL_W (wx, wy)

x, y
(Input) INTEGER(2). Viewport coordinates for pixel position.

wx, wy
(Input) REAL(8). Window coordinates for pixel position.

Results:
The result type is INTEGER(2). The result is the pixel color index if successful; otherwise, –1 (for example, if the pixel lies outside the clipping region).

Color routines without the RGB suffix, such as GETPIXEL, use color indexes, not true color values, and limit you to colors in the palette, at most 256. To access all system colors, use SETPIXELRG to specify an explicit Red-Green-Blue value and retrieve the value with GETPIXELRGB.

NOTE. The GETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the GetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWINS$GetPixel. For more information, see “Special Naming Convention for Certain QuickWin and Win32 Graphics Routines” in Building Applications.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETPIXELRGB, GETPIXELRGB_W", "GRSTATUS", "REMAPPALETTERGB", "REMAPALLPALETTERGB", "SETCOLOR", "GETPIXELS", "SETPIXEL, SETPIXEL_W"

GETPIXELRGB, GETPIXELRGB_W

Graphics Functions: Return the Red-Green-Blue (RGB) color value of the pixel at a specified location. These functions are only available on Windows® systems.

Module: USE IFQWIN

Syntax
result = GETPIXELRGB (x, y)
result = GETPIXELRGB_W (wx, wy)

\( x, y \)

(Input) INTEGER(2). Viewport coordinates for pixel position.

\( wx, wy \)

(Input) REAL(8). Window coordinates for pixel position.

**Results:**

The result type is INTEGER(4). The result is the pixel’s current RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETPIXELRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>R</th>
<th>R</th>
<th>R</th>
<th>R</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>( \text{COLOR} )</td>
<td>( B )</td>
<td>( B )</td>
<td>( B )</td>
<td>( B )</td>
<td>( G )</td>
<td>( G )</td>
<td>( G )</td>
<td>( G )</td>
<td>( R )</td>
<td>( R )</td>
<td>( R )</td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF0’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

GETPIXELRGB returns the true color value of the pixel, set with SETPIXELRGB, SETCOLORRGB, SETBKGDRGB, or SETTEXTCOLORRGB, depending on the pixel’s position and the current configuration of the screen.

SETPIXELRGB (and the other RGB color selection functions SETCOLORRGB, SETBKGDRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKG, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “SETPIXELRGB, SETPIXELRGB_W”, “GETPIXELRGB”, “GETPIXELRGB_W”, “GETPIXEL”, “GETPIXEL_W”

**Example**

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) pixcolor, rseed
INTEGER(2) status
REAL rnd1, rnd2
LOGICAL(4) winstat
TYPE (windowconfig) wc
CALL GETTIM (status, status, status, INT2(rseed))
CALL SEED (rseed)
CALL RANDOM (rnd1)
CALL RANDOM (rnd2)
! Get the color index of a random pixel, normalized to
! be in the window. Then set current color to that
! pixel color.
winstat = GETWINDOWCONFIG(wc)
xnum = wc%numxpixels
ynum = wc%numypixels
pixcolor = GETPIXELRGB( INT2( rnd1*xnum ), INT2( rnd2*ynum ))
status = SETCOLORRGB (pixcolor)
END

GETPIXELS

Graphics Subroutine: Returns the color indexes of multiple pixels. This subroutine is only available on Windows® systems.
Module: USE IFQWIN
Syntax
CALL GETPIXELS (n, x, y, color)

n
(Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other arguments.
x, y
(Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to get.
color
(Output) INTEGER(2). Array to be filled with the color indexes of the pixels at x and y.
GETPIXELS fills in the array color with color indexes of the pixels specified by the two input arrays x and y. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If the pixel is outside the clipping region, the value placed in the color array is undefined. Calls to GETPIXELS with n less than 1 are ignored. GETPIXELS is a much faster way to acquire multiple pixel color indexes than individual calls to GETPIXEL.

The range of possible pixel color index values is determined by the current video mode and palette, at most 256 colors. To access all system colors you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function such as SETPIXELSRGB and retrieve the value with GETPIXELSRGB, rather than a palette index with a non-RGB color function.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETPIXELSRGB", "SETPIXELSRGB", "GETPIXEL, GETPIXEL_W", "SETPIXELS"

GETPIXELSRGB

Graphics Subroutine: Returns the Red-Green-Blue (RGB) color values of multiple pixels. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL GETPIXELSRGB (n, x, y, color)

n
(Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other argument arrays.

x, y
(Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels.

color
(Output) INTEGER(4). Array to be filled with RGB color values of the pixels at x and y.

GETPIXELS fills in the array color with the RGB color values of the pixels specified by the two input arrays x and y. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the values you retrieve with GETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O O</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>G</td>
<td>G</td>
<td>G</td>
<td>R</td>
<td>R</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELSRGB is a much faster way to acquire multiple pixel RGB colors than individual calls to GETPIXELRGB. GETPIXELSRGB returns an array of true color values of multiple pixels, set with SETPIXELSRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixels' positions and the current configuration of the screen.

SETPIXELSRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "SETPIXELSRGB", "GETPIXELRGB, GETPIXELRGB_W", "GETPIXELS", "SETPIXELS"

Example

```fortran
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) color(50), result
INTEGER(2) x(50), y(50), status
TYPE (xycoord) pos
result = SETCOLORRGB(Z'FF')
CALL MOVETO(INT2(0), INT2(0), pos)
status = LINETO(INT2(100), INT2(200))
```
! Get 50 pixels at line 30 in viewport
DO i = 1, 50
    x(i) = i-1
    y(i) = 30
END DO
CALL GETPIXELSRGB(300, x, y, color)
! Move down 30 pixels and redisplay pixels
DO i = 1, 50
    y(i) = y(i) + 30
END DO
CALL SETPIXELSRGB (50, x, y, color)
END

GETPOS, GETPOSI8

Portability Functions: Return the current position of a file.
Module: USE IFPORT
Syntax
result = GETPOS (lunit)
result = GETPOSI8 (lunit)
lunit
(Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and
the file must be connected.
Results:
The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the
offset, in bytes, from the beginning of the file. If an error occurs, the result value is –1 and the
following error code is returned in errno:
EINV AL: lunit is not a valid unit number, or is not open.
These functions are equivalent to “FTELL, FTELLI8”.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

GETSTATUSFPQQ

Portability Subroutine: Returns the floating-point processor status word.
Module: USE IFPORT

Syntax

CALL GETSTATUSFPQQ (status)

status
(Output) INTEGER(2). Floating-point processor status word.

The floating-point status word shows whether various floating-point exception conditions have occurred. Intel® Visual Fortran initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>$'003F'$</td>
<td>Status Mask (set all flags to 1)</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>$'0001'$</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>$'0002'$</td>
<td>A denormal (very small number) occurred</td>
</tr>
<tr>
<td>FPSW$ZERODIVIDE</td>
<td>$'0004'$</td>
<td>A divide by zero occurred</td>
</tr>
<tr>
<td>FPSW$OVERFLOW</td>
<td>$'0008'$</td>
<td>An overflow occurred</td>
</tr>
<tr>
<td>FPSW$UNDERFLOW</td>
<td>$'0010'$</td>
<td>An underflow occurred</td>
</tr>
<tr>
<td>FPSW$INEXACT</td>
<td>$'0020'$</td>
<td>Inexact precision occurred</td>
</tr>
</tbody>
</table>

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

For a full discussion of the floating-point status word, exceptions, and error handling, see “The Floating-Point Environment” in *Building Applications.*
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

Example

! Program to demonstrate GETSTATUSFPQQ
USE IFPORT
INTEGER(2) status
CALL GETSTATUSFPQQ(status)
! check for divide by zero
IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
  WRITE (*,*) 'Divide by zero occurred. Look &
  for NaN or signed infinity in resultant data.'
END IF
END

GETSTRQQ

Run-time Function: Reads a character string from the keyboard using buffered input.

Module: USE IFCORE

Syntax

result = GETSTRQQ (buffer)

buffer

(Output) Character*(*). Character string returned from keyboard, padded on the right with blanks.

Results:
The result type is INTEGER(4). The result is the number of characters placed in buffer.
The function does not complete until you press Return or Enter.

Compatibility

END IF
END

run: '
'

ELSE
: ', result, 'h'

GETTEXTCOLOR
Graphics Function: Returns the current text color index. This function is only available on
Windows* systems.
Module: USE IFQWIN
Syntax
result = GETTEXTCOLOR( )
Results:
The result type is INTEGER(2). It is the current text color index.
GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR
affects text output with OUTTEXT, WRITE, and PRINT. The background color index is set with
SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the
background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color
functions use color indexes, not true color values, and limit the user to colors in the palette, at most
256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and
SETCOLORRGB.

2-144


The default text color index is 15, which is associated with white unless the user remaps the palette.

---

**NOTE.** The GETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the GetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWINSGetTextColor. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

---

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “OUTTEXT”, “REMAPPALETTERGB”, “SETCOLOR”, “SETTEXTCOLOR”

---

**GETTEXTCOLORRGB**

**Graphics Function:** Returns the Red-Green-Blue (RGB) value of the current text color (used with OUTTEXT, WRITE and PRINT). This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

\[
\text{result} = \text{GETTEXTCOLORRGB}() \\
\]

**Results:**

The result type is INTEGER(4). It is the RGB value of the current text color. In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O O O B B B B B B G G G G G G R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFFFF' full-intensity for all three, resulting in bright white.
GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB. The RGB color value used for graphics is set and returned with SETCOLORRGB and GETCOLORRGB. SETCOLORRGB controls the color used by the graphics function OUTGTEXT, while SETTEXTCOLORRGB controls the color used by all other text output functions. The RGB background color value for both text and graphics is set and returned with SETBKCOLORRGB and GETBKCOLORRGB.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETCOLORRGB) sets the color to a color value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “SETTEXTCOLORRGB”, “GETBKCOLORRGB”, “GETCOLORRGB”, “GETTEXTCOLOR”

Example
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) oldtextc, oldbackc, temp
TYPE (rccoord) curpos
! Save color settings
oldtextc = GETTEXTCOLORRGB()
oldbackc = GETBKCOLORRGB()
CALL CLEARSCREEN( $GCLEARSCREEN )
! Reset colors
temp = SETTEXTCOLORRGB(Z'00FFFF') ! full red + full green
    ! = full yellow text
    
temp = SETBKCOLORRGB(Z'FF0000')    ! blue background
CALL SETTEXTPOSITION( INT2(4), INT2(15), curpos)
CALL OUTTEXT( 'Hello, world')
! Restore colors
    
temp = SETTEXTCOLORRGB(oldtextc)
temp = SETBKCOLORRGB(oldbackc)
GETTEXTPOSITION

Graphics Subroutine: Returns the current text position. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL GETTEXTPOSITION (t)

(t) (Output) Derived type rccord. Current text position. The derived type rccord is defined in IFQWIN.F90 as follows:

TYPE rccord
   INTEGER(2) row   ! Row coordinate
   INTEGER(2) col   ! Column coordinate
END TYPE rccord

The text position given by coordinates (1, 1) is defined as the upper-left corner of the text window. Text output from the OUTTEXT function (and WRITE and PRINT statements) begins at the current text position. Font text is not affected by the current text position. Graphics output, including OUTGTEXT output, begins at the current graphics output position, which is a separate position returned by GETCURRENTPOSITION.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “SETTEXTPOSITION”, “OUTTEXT”, “GETCURRENTPOSITION”, “GETCURRENTPOSITION_W”, “SETTEXTWINDOW”, the WRITE statement in the Language Reference

Example

! Build as QuickWin or Standard Graphics

USE IFQWIN

TYPE (rccord) textpos

CALL GETTEXTPOSITION (textpos)

END
GETTEXTWINDOW

Graphics Subroutine: Finds the boundaries of the current text window. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL GETTEXTWINDOW (r1, c1, r2, c2)

r1, c1
(Output) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

r2, c2
(Output) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

Output from OUTTEXT and WRITE is limited to the text window. By default, this is the entire window, unless the text window is redefined by SETTEXTWINDOW.

The window defined by SETTEXTWINDOW has no effect on output from OUTGTEXT.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “GETTEXTPOSITION”, “OUTTEXT”, “SCROLLTEXTWINDOW”, “SETTEXTPOSITION”, “SETTEXTWINDOW”, “WRAPON”, the WRITE statement in the Language Reference

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) top, left, bottom, right
DO i = 1, 10
  WRITE(*,*) "Hello, world"
END DO

! Save text window position
CALL GETTEXTWINDOW (top, left, bottom, right)

! Scroll text window down seven lines
CALL SCROLLTEXTWINDOW (INT2(-7))

! Restore text window
CALL SETTEXTWINDOW (top, left, bottom, right)
WRITE(*,*) "At beginning again"
END
GETTIM

**Portability Subroutine:** Returns the time.

**Module:** USE IFPORT

**Syntax**

```call gettim (ihr, imin, isec, i100th)```

- `ihr` (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
- `imin` (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
- `isec` (Output) INTEGER(4) or INTEGER(2). Second (0-59).
- `i100th` (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

**See Also:** “GETDAT”, “SETDAT”, “SETTIM”

**Example**

See the example in “GETDAT”.

GETTIMEOFDAY

**Portability Subroutine:** Returns seconds and microseconds since 00:00 Jan 1, 1970.

**Module:** USE IFPORT

**Syntax**

```call gettimeofday (ret, err)```

- `ret` (Output) INTEGER(4). One-dimensional array with 2 elements used to contain numeric time data. The elements of `ret` are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ret(1)</td>
<td>Seconds</td>
</tr>
<tr>
<td>ret(2)</td>
<td>Microseconds</td>
</tr>
</tbody>
</table>
err
(Output) INTEGER(4).
If an error occurs, err contains a value equal to –1 and array ret contains zeros.
On Windows* systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

GETUID

Portability Function: Returns the user ID of the calling process.
Module: USE IFPORT
Syntax
   result = GETUID( )
Results:
The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:
   • On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
     Note that on Windows systems, domain accounts and local accounts can overlap.
   • On Linux* and Mac OS* systems, this function returns the user identity for the current process.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example
USE IFPORT
integer(4) istat
ISTAT = GETUID( )

GETUNITQQ

QuickWin Function: Returns the unit number corresponding to the specified Windows* handle. This function is only available on Windows systems.
Module: USE IFQWIN
Syntax

\[
\text{result} = \text{GETUNITQQ}(\text{whandle})
\]

\text{whandle}

(Input) \text{INTEGER(4)} on IA-32 processors; \text{INTEGER(8)} on Intel Itanium and Intel EM64T processors. The Windows handle to the window; this is a unique ID.

Results:
The result type is \text{INTEGER(4)}. The result is the unit number corresponding to the specified Windows handle. If \text{whandle} does not exist, it returns \(-1\).

This routine is the inverse of GETHWNDQQ.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "GETHWNDQQ", "Using QuickWin" in \textit{Building Applications}

GETVIEWCOORD, GETVIEWCOORD\_W

\textbf{Graphics Subroutines:} Translate physical coordinates or window coordinates to viewport coordinates. These subroutines are only available on Windows\* systems.

\textbf{Module:} USE IFQWIN

Syntax

\[
\begin{align*}
\text{CALL GETVIEWCOORD}(x, y, t) \\
\text{CALL GETVIEWCOORD\_W}(wx, wy, wt)
\end{align*}
\]

\textit{x, y}

(Input) \text{INTEGER(2)}. Physical coordinates to be converted to viewport coordinates.

\textit{t}

(Output) Derived type \textit{xycoord}. Viewport coordinates. The \textit{xycoord} derived type is defined in \texttt{IFQWIN.F90} as follows:

\[
\begin{align*}
\text{TYPE xycoord} \\
\text{ INTEGER(2) xcoord } ! x\text{-coordinate} \\
\text{ INTEGER(2) ycoord } ! y\text{-coordinate}
\end{align*}
\]

\texttt{xycoord}

\textit{wx, wy}

(Input) \text{REAL(8)}. Window coordinates to be converted to viewport coordinates.
wt

(Output) Derived type wxycoord. Window coordinates. The derived type wxycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE wxycoord
   REAL(8) wx ! x-coordinate
   REAL(8) wy ! y-coordinate
END TYPE wxycoord
```

Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Physical coordinates refer to the whole screen. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area. For a more complete discussion of coordinate systems, see "Understanding Coordinate Systems" in Building Applications.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: "GETPHYSCOORD", "GETWINDOWCOORD"

Example

See the example program in "GETPHYSCOORD".

GETWINDOWCONFIG

QuickWin Function: Returns the properties of the current window. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

```fortran
result = GETWINDOWCONFIG (wc)
```

wc

(Output) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE windowconfig
   INTEGER(2) numxpixels ! Number of pixels on x-axis
   INTEGER(2) numypixels ! Number of pixels on y-axis
   INTEGER(2) numtextcols ! Number of text columns available
   INTEGER(2) numtextrows ! Number of text rows available
   INTEGER(2) numcolors ! Number of color indexes
END TYPE windowconfig
```
INTEGER(4) fontsize ! Size of default font. Set to
! QWIN$EXTENDFONT when specifying
! extended attributes, in which
! case extendfontsize sets the
! font size

CHARACTER(80) title ! The window title

INTEGER(2) bitsperpixel ! The number of bits per pixel
INTEGER(2) numvideopages ! Unused
INTEGER(2) mode ! Controls scrolling mode
INTEGER(2) adapter ! Unused
INTEGER(2) monitor ! Unused
INTEGER(2) memory ! Unused
INTEGER(2) environment ! Unused

! The next three parameters provide extended font attributes.
!
CHARACTER(32) extendfontname ! The name of the desired font
INTEGER(4) extendfontsize ! Takes the same values as fontsize,
! when fontsize is set to
! QWIN$EXTENDFONT
INTEGER(4) extendfontattributes ! Font attributes such as bold
! and italic

END TYPE windowconfig

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE. (for example, if there is no active child window).

GETWINDOWCONFIG returns information about the active child window. If you have not set the window properties with SETWINDOWCONFIG, GETWINDOWCONFIG returns default window values.

A typical set of values would be 1024 x pixels, 768 y pixels, 128 text columns, 48 text rows, and a font size of 8x16 pixels. The resolution of the display and the assumed font size of 8x16 pixels generates the number of text rows and text columns.

The resolution (in this case, 1024 x pixels by 768 y pixels) is the size of the virtual window. To get the size of the physical window visible on the screen, use GETWSIZEQQ. In this case, GETWSIZEQQ returned the following values: (0,0) for the x and y position of the physical window, 25 for the height or number of rows, and 71 for the width or number of columns.
The number of colors returned depends on the video drive. The window title defaults to "Graphic1" for the default window. All of these values can be changed with SETWINDOWCONFIG.

Note that the bitsperpixel field in the windowconfig derived type is an output field only, while the other fields return output values to GETWINDOWCONFIG and accept input values from SETWINDOWCONFIG.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: "GETWSIZEQQ", "SETWINDOWCONFIG", "SETACTIVEQQ", "Using QuickWin" in Building Applications

Example
!Build as QuickWin or Standard Graphics App.
USE IFQWIN
LOGICAL(4) status
TYPE (windowconfig) wc
status = GETWINDOWCONFIG(wc)
IF(wc%numtextrows .LT. 10) THEN
  wc%numtextrows = 10
  status = SETWINDOWCONFIG(wc)
  IF(.NOT. status ) THEN ! if setwindowconfig error
    status = SETWINDOWCONFIG(wc) ! reset
    ! setwindowconfig with corrected values
  END IF
  status = GETWINDOWCONFIG(wc)
  IF(wc%numtextrows .NE. 10) THEN
    WRITE(*,*) 'Error: Cannot increase text rows to 10'
  END IF
END IF
END IF
END IF
END

GETWINDOWCOORD

Graphics Subroutine: Converts viewport coordinates to window coordinates. This subroutine is only available on Windows® systems.

Module: USE IFQWIN
**Syntax**

CALL GETWINDOWCOORD (x, y, wt)

\(x, y\)

(Input) INTEGER(2). Viewport coordinates to be converted to window coordinates.

\(wt\)

(Output) Derived type \texttt{wxycoord}. Window coordinates. The \texttt{wxycoord} derived type is defined in \texttt{IFQWIN.F90} as follows:

```fortran
TYPE wxycoord
   REAL(8) wx   ! x-coordinate
   REAL(8) wy   ! y-coordinate
END TYPE wxycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with \texttt{SETVIEWPORT}. Both take integer coordinate values. Window coordinates refer to a window sized with \texttt{SETWINDOW} or \texttt{SETWSIZEQQ}. Window coordinates are floating-point values and allow easy scaling of data to the window area. For a more complete discussion of coordinate systems, see "Understanding Coordinate Systems" in \textit{Building Applications}.

See the example program in "\texttt{GETPHYSCOORD}".

---

**GETWRITEMODE**

**Graphics Function:** Returns the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = GETWRITEMODE ( )
```

**Results:**

The result type is INTEGER(2). The result is the current write mode. Possible return values are:

---
• $GPSET– Causes lines to be drawn in the current graphics color. (default)
• $GAND – Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
• $GOR – Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
• $GPRESET – Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
• $GXOR – Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

The default value is $GPSET. These constants are defined in IFQWIN.F90.

The write mode is set with SETWRITEMODE.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

Example
! Build as QuickWin or Standard Graphics App.
USE IFQWIN
  INTEGER(2) mode
  mode = GETWRITEMODE()
END

GETWSIZEQQ

QuickWin Function: Returns the size and position of a window. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = GETWSIZEQQ (unit, ireq, winfo)

unit

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5 and 6 refer to the default startup window only if you have not explicitly opened them with the OPEN statement. To access information about the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW, defined in IFQWIN.F90.
ireq

(Input) INTEGER(4). Specifies what information is obtained. The following symbolic constants, defined in IFQWIN.F90, are available:

• QWIN$SIZEMAX – Gets information about the maximum window size.
• QWIN$SIZECURR – Gets information about the current window size.

winfo

(Output) Derived type qwinfo. Physical coordinates of the window’s upper-left corner, and the current or maximum height and width of the window’s client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

```fortran
TYPE QWINFO
    INTEGER(2) TYPE ! request type (controls
                   !  SETWSIZEQQ)
    INTEGER(2) X     ! x coordinate for upper left
    INTEGER(2) Y     ! y coordinate for upper left
    INTEGER(2) H     ! window height
    INTEGER(2) W     ! window width
END TYPE QWINFO
```

Results:

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width returned for a frame window reflects the size in pixels of the client area excluding any borders, menus, and status bar at the bottom of the frame window. You should adjust the values used in SETWSIZEQQ to take this into account.

The client area is the area actually available to place child windows.

Compatibility

QUICKWIN GRAPHICS LIB

GMTIME

Portability Subroutine: Returns the Greenwich mean time in an array of time elements.

Module: USE IFPORT
Syntax

CALL Gmtime (stime, tarray)

stime
(Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.

tarray
(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of tarray are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tarray(1)</td>
<td>Seconds (0-61, where 60-61 can be returned for leap seconds)</td>
</tr>
<tr>
<td>tarray(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>tarray(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>tarray(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>tarray(5)</td>
<td>Month (0-11)</td>
</tr>
<tr>
<td>tarray(6)</td>
<td>Number of years since 1900</td>
</tr>
<tr>
<td>tarray(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>tarray(8)</td>
<td>Day of year (0-365)</td>
</tr>
<tr>
<td>tarray(9)</td>
<td>Daylight saving flag (0 if standard time, 1 if daylight saving time)</td>
</tr>
</tbody>
</table>

CAUTION. This subroutine may cause problems with the year 2000. Use the DATE_AND_TIME intrinsic subroutine instead (see the Language Reference).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
! 00:00:00 GMT January 1, 1970
stime = time()
CALL Gmtime (stime, timearray)
print *, timearray
GRSTATUS

**Graphics Function:** Returns the status of the most recently used graphics routine. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```
result = GRSTATUS ( )
```

**Results:**
The result type is INTEGER(2). The result is the status of the most recently used graphics function.

Use GRSTATUS immediately following a call to a graphics routine to determine if errors or warnings were generated. Return values less than 0 are errors, and values greater than 0 are warnings.

The following symbolic constants are defined in the IFQWIN.F90 module file for use with GRSTATUS:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GRFILEWRITEERROR</td>
<td>Error writing bitmap file</td>
</tr>
<tr>
<td>$GRFILEOPENERROR</td>
<td>Error opening bitmap file</td>
</tr>
<tr>
<td>$GRIMAGEREADERROR</td>
<td>Error reading image</td>
</tr>
<tr>
<td>$GRBITMAPDISPLAYERROR</td>
<td>Error displaying bitmap</td>
</tr>
<tr>
<td>$GRBITMAPTOOLARGE</td>
<td>Bitmap too large</td>
</tr>
<tr>
<td>$GRIMPROPERBITMAPFORMAT</td>
<td>Improper format for bitmap file</td>
</tr>
<tr>
<td>$GRFILEREADERROR</td>
<td>Error reading file</td>
</tr>
<tr>
<td>$GRNOBITMAPFILE</td>
<td>No bitmap file</td>
</tr>
<tr>
<td>$GRINVALIDIMAGEBUFFER</td>
<td>Image buffer data inconsistent</td>
</tr>
<tr>
<td>$GRINSUFFICIENTMEMORY</td>
<td>Not enough memory to allocate buffer or to complete a fill operation</td>
</tr>
<tr>
<td>$GRINVALIDPARAMETER</td>
<td>One or more parameters invalid</td>
</tr>
<tr>
<td>$GRMODENOTSUPPORTED</td>
<td>Requested video mode not supported</td>
</tr>
<tr>
<td>$GRERROR</td>
<td>Graphics error</td>
</tr>
<tr>
<td>$GROK</td>
<td>Success</td>
</tr>
<tr>
<td>$GRNOOUTPUT</td>
<td>No action taken</td>
</tr>
</tbody>
</table>
After a graphics call, compare the return value of GRSTATUS to $GROK to determine if an error has occurred. For example:

```fortran
IF ( GRSTATUS .LT. $GROK ) THEN
  ! Code to handle graphics error goes here
ENDIF
```

The following routines cannot give errors, and they all set GRSTATUS to $GROK:

<table>
<thead>
<tr>
<th>Function</th>
<th>Possible GRSTATUS error codes</th>
<th>Possible GRSTATUS warning codes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISPLAYCORSOR</td>
<td>GETCOLORRGB</td>
<td>GTTEXTWINDOW</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>GETTEXTCOLOR</td>
<td>OUTFTEXT</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>GETTEXTCOLORRGB</td>
<td>WRAPON</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>GETTEXTPOSITION</td>
<td></td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>$GRERROR</td>
<td></td>
</tr>
<tr>
<td>GETFILLMASK</td>
<td>$GRERROR, $GRINVALPARAMETER</td>
<td></td>
</tr>
<tr>
<td>GETFONTINFO</td>
<td>$GRERROR</td>
<td></td>
</tr>
<tr>
<td>GETGTEXTTEXTENT</td>
<td>$GRERROR</td>
<td></td>
</tr>
<tr>
<td>GETIMAGE</td>
<td>$GRINSUFFICIENTMEMORY</td>
<td></td>
</tr>
<tr>
<td>GETPIXEL</td>
<td>$GRBITMAPTOOLARGE</td>
<td></td>
</tr>
<tr>
<td>GETPIXELRGB</td>
<td>$GRBITMAPTOOLARGE</td>
<td></td>
</tr>
</tbody>
</table>

The following table lists some other routines with the error or warning messages they produce for GRSTATUS:

<table>
<thead>
<tr>

</tbody>
</table>
HOSTNAM

Portability Function: Returns the current host computer name. This function can also be specified as HOSTNM.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{HOSTNAM} (\text{name})
\]

name

(Output) Character\(^{(*)}\). Name of the current host. Should be at least as long as MAX_HOSTNAM_LENGTH + 1. MAX_HOSTNAM_LENGTH is defined in the IFPORT module.

Results:

The result type is INTEGER(4). The result is zero if successful. If name is not long enough to contain all of the host name, the function truncates the host name and returns −1.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
**IDATE**

**Portability Subroutine:** Returns the month, day, and year of the current system.

**Module:** USE IFPORT

**Syntax**

CALL IDATE (i, j, k)

-or-

CALL IDATE (iarray)

i
(Output) INTEGER(4). The current system month.

j
(Output) INTEGER(4). The current system day.

k
(Output) INTEGER(4). The current system year as an offset from 1900.

iarray
(Output) INTEGER(4). Three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is greater than or equal to 1969 and is returned as 2 digits.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**See Also:** “DATE”, “GETDAT”, the DATE_AND_TIME and IDATE subroutines in the Language Reference

**Example**

```fortran
use IFPORT
  integer(4) imonth, iday, iyear, datarray(3)
! If the date is July 11, 1999:
  CALL IDATE(IMONTH, IDAY, IYEAR)
! sets IMONTH to 7, IDAY to 11 and IYEAR to 99.
  CALL IDATE(DATARRAY)
! datarray is (/11,7,99/)
```

**NOTE.** IDATE is an intrinsic procedure unless you specify USE IFPORT.
IDATE4

**Portability Subroutine:** Returns the month, day, and year of the current system.

**Module:** USE IFPORT

**Syntax**

CALL IDATE4 (i, j, k)

-or-

CALL IDATE4 (iarray)

\( i \)

(Output) INTEGER(4). The current system month.

\( j \)

(Output) INTEGER(4). The current system day.

\( k \)

(Output) INTEGER(4). The current system year as an offset from 1900.

\( iarray \)

(Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

IDFLOAT

**Portability Function:** Converts an INTEGER(4) variable to double-precision real type.

**Module:** USE IFPORT

**Syntax**

result = IDFLOAT (i)

\( i \)

(Input) Must be of type INTEGER(4).

**Results:**

The result type is double-precision real (REAL(8) or REAL*8).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
## IEEE_FLAGS

**Portability Function:** Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of IEEE Standard 754-1985 arithmetic in a Fortran program.

**Module:** USE IFPORT

**Syntax**

```fortran
result = IEEE_FLAGS (action, mode, in, out)
```

- **action**
  - (Input) Character*(*)). One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.

- **mode**
  - (Input) Character*(*)). One of the following literal values: 'direction', 'precision', or 'exception'. The value 'precision' is only allowed on IA-32 and Intel® EM64T systems.

- **in**
  - (Input) Character*(*)). One of the following literal values: 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive', 'extended', 'double', 'single', or ' ', which represents an unused (null) value.

- **out**
  - (Output) Must be at least CHARACTER*9. One of the literal values listed for *in*.

The descriptions for the values allowed for *in* and *out* can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nearest'</td>
<td>Rounding direction flags</td>
</tr>
<tr>
<td>'tozero'</td>
<td></td>
</tr>
<tr>
<td>'negative'</td>
<td></td>
</tr>
<tr>
<td>'positive'</td>
<td></td>
</tr>
<tr>
<td>'single'</td>
<td>Rounding precision flags</td>
</tr>
<tr>
<td>'double'</td>
<td></td>
</tr>
<tr>
<td>'extended'</td>
<td></td>
</tr>
<tr>
<td>'inexact'</td>
<td>Math exception flags</td>
</tr>
<tr>
<td>'underflow'</td>
<td></td>
</tr>
<tr>
<td>'overflow'</td>
<td></td>
</tr>
<tr>
<td>'division'</td>
<td></td>
</tr>
<tr>
<td>'invalid'</td>
<td></td>
</tr>
</tbody>
</table>

**See Also:** the intrinsic function DFLOAT in the *Language Reference*
The values for `in` and `out` depend on the `action` and `mode` they are used with. The interaction of the parameters can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'all'</td>
<td>All five math exception flags above</td>
</tr>
<tr>
<td>'common'</td>
<td>The math exception flags: 'invalid', 'division', 'overflow', and 'underflow'</td>
</tr>
</tbody>
</table>

The values for `in` and `out` depend on the `action` and `mode` they are used with. The interaction of the parameters can be summarized as follows:

<table>
<thead>
<tr>
<th>action</th>
<th>mode</th>
<th>in</th>
<th>out</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>One of 'nearest', 'tozero', 'negative', or 'positive'</td>
<td>Tests rounding direction settings. Returns the current setting, or 'not available'.</td>
</tr>
<tr>
<td></td>
<td>'exception'</td>
<td>Null (' ')</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Tests math exception settings. Returns the current setting, or 0.</td>
</tr>
<tr>
<td></td>
<td>'precision'</td>
<td>Null (' ')</td>
<td>One of 'single ', 'double ', or 'extended'</td>
<td>Tests rounding precision settings. Returns the current setting, or 'not available'.</td>
</tr>
<tr>
<td>SET</td>
<td>'direction'</td>
<td>One of 'nearest', 'tozero', 'negative', or 'positive'</td>
<td>Null (' ')</td>
<td>Sets a rounding direction.</td>
</tr>
<tr>
<td></td>
<td>'exception'</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Null (' ')</td>
<td>Sets a floating-point math exception.</td>
</tr>
<tr>
<td></td>
<td>'precision'</td>
<td>One of 'single ', 'double ', or 'extended'</td>
<td>Null (' ')</td>
<td>Sets a rounding precision.</td>
</tr>
</tbody>
</table>
IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.

The flags information is returned as a set of 1-bit flags.

### Examples

The following example gets the highest priority exception that has a flag raised. It passes the input argument *in* as a null string:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```fortran
USE IFPORT
INTEGER*4 iflag
```

### Results

<table>
<thead>
<tr>
<th>action</th>
<th>mode</th>
<th>in</th>
<th>out</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEAR</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears the <em>mode</em>. Sets rounding to 'nearest'. Returns 0 if successful.</td>
</tr>
<tr>
<td></td>
<td>'exception'</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Null (' ')</td>
<td>Clears the <em>mode</em>. Returns 0 if successful.</td>
</tr>
<tr>
<td></td>
<td>'precision'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears the <em>mode</em>. Sets precision to 'double' (W<em>32, W</em>64) or 'extended' (L<em>X, M</em>X32). Returns 0 if successful.</td>
</tr>
<tr>
<td>CLEARALL</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears all flags. Sets rounding to 'nearest', sets precision to 'double' (W<em>32, W</em>64) or 'extended' (L<em>X, M</em>X32), and sets all exception flags to 0. Returns 0 if successful.</td>
</tr>
</tbody>
</table>
CHARACTER*1 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)

The following example sets the rounding direction to the default ('nearest'):
USE IFPORT
INTEGER*4 iflag
CHARACTER*1 out, in
iflag = ieee_flags('clear','direction', '', '' )

The following example clears all exceptions:
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear','exception', 'all', '' )

The following example restores default direction and precision settings, and sets all exception flags to 0:
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '' )

The following example detects an underflow exception:
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'

**IEEE_HANDLER**

**Portability Function:** Establishes a handler for IEEE exceptions.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{IEEE_HANDLER (action, exception, handler)}
\]

**action**

(Input) Character*(*)). One of the following IEEE actions: 'GET', 'SET', or 'CLEAR'. For more details on these actions, see IEEE_FLAGS.
exception

(Input) Character*(*)\. One of the following IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all' (which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division'). The flags 'all' or 'common' should only be used for actions SET or CLEAR. For more details on these flags, see IEEE_FLAGS.

handler

(Input) The address of an external signal-handling routine.

Results:
The result type is INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appear in the following table (defined in the IFPORT module):

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>Invalid operation</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>Divide-by-zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>Numeric overflow</td>
</tr>
<tr>
<td>FPE$UNDERFLOW</td>
<td>Numeric underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>Inexact result (precision)</td>
</tr>
</tbody>
</table>

'GET' returns the location of the current handler routine for exception cast to an INTEGER.

See Also: "IEEE_FLAGS"

Example

The following example creates a handler routine and sets it to trap divide-by-zero:

```fortran
PROGRAM TEST_IEEE
  REAL :: X, Y, Z
  CALL FPE_SETUP
  X = 0.
  Y = 1.
  Z = Y / X
```

```fortran
FPE$INVALID Invalid operation
FPE$ZERODIVIDE Divide-by-zero
FPE$OVERFLOW Numeric overflow
FPE$UNDERFLOW Numeric underflow
FPE$INEXACT Inexact result (precision)
```
END PROGRAM

SUBROUTINE FPE_SETUP
USE IFPORT
IMPLICIT NONE
INTERFACE
  SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
    INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
  END SUBROUTINE
END INTERFACE
INTEGER IR
IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE FPE_SETUP

SUBROUTINE FPE_HANDLER(SIG, CODE)
USE IFPORT
IMPLICIT NONE
INTEGER SIG, CODE
IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *, 'Occurred divide by zero.'
CALL ABORT
END SUBROUTINE FPE_HANDLER

IERRNO

Portability Function: Returns the number of the last detected error from any routines in the IFPORT module that return error codes.

Module: USE IFPORT

Syntax
result = IERRNO ( )

Results:
The result type is INTEGER(4). The result value is the last error code from any portability routines that return error codes. These error codes are analogous to errno on a Linux* or Mac OS* system. The module IFPORT.F90 provides parameter definitions for the following errno names (typically found in errno.h on Linux systems):

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>1</td>
<td>Insufficient permission for operation</td>
</tr>
<tr>
<td>ENOENT</td>
<td>2</td>
<td>No such file or directory</td>
</tr>
</tbody>
</table>
The value returned by IERRNO is updated only when an error occurs. For example, if an error occurs on a GETLOG call and then two CHMOD calls succeed, a subsequent call to IERRNO returns the error for the GETLOG call.

Examine IERRNO immediately after returning from a portability routine. Other Fortran routines, as well as any Windows* APIs, can also change the error code to an undefined value. IERRNO is set on a per thread basis.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
CHARACTER*20 username
INTEGER(4) ierrval
ierrval=0 !initialize return value
CALL GETLOG(username)
IF (IERRNO( ) == ierrval) then
   print *, 'User name is ',username
   exit
ELSE
   ierrval = ierrno()
   print *, 'Error is ',ierrval
END IF

IFLOATI, IFLOATJ

Portability Functions: Convert an integer to single-precision real type.
**Module:** USE IFPORT

**Syntax**

result = IFLOATI (i)
result = IFLOATJ (j)

*i*  
(Input) Must be of type INTEGER(2).

*j*  
(Input) Must be of type INTEGER(4).

**Results:**

The result type is single-precision real (REAL(4) or REAL*4).

**Compatibility**

CONSOL|E  STAND|ARD  GRAPHIC|S  QUICKWIN  GRAPHIC|S  WIND|OWS  DLL  LIB

**See Also:** the DFLOAT intrinsic function in the *Language Reference*

---

**IMAGESIZE, IMAGESIZE_W**

**Graphics Functions:** Return the number of bytes needed to store the image inside the specified bounding rectangle. IMAGESIZE is useful for determining how much memory is needed for a call to GETIMAGE. These functions are only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

result = IMAGESIZE (x1, y1, x2, y2)
result = IMAGESIZE_W (wx1, wy1, wx2, wy2)

*x1*, *y1*  
(Input) INTEGER(2). Viewport coordinates for upper-left corner of image.

*x2*, *y2*  
(Input) INTEGER(2). Viewport coordinates for lower-right corner of image.

*wx1*, *wy1*  
(Input) REAL(8). Window coordinates for upper-left corner of image.

*wx2*, *wy2*  
(Input) REAL(8). Window coordinates for lower-right corner of image.

**Results:**

The result type is INTEGER(4). The result is the storage size of an image in bytes.
IMAGESIZE defines the bounding rectangle in viewport-coordinate points \((x_1, y_1)\) and \((x_2, y_2)\).

IMAGESIZE_W defines the bounding rectangle in window-coordinate points \((wx_1, wy_1)\) and \((wx_2, wy_2)\).

IMAGESIZE_W defines the bounding rectangle in terms of window-coordinate points \((wx_1, wy_1)\) and \((wx_2, wy_2)\).

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETIMAGE, GETIMAGE_W”, “GRSTATUS”, “PUTIMAGE, PUTIMAGE_W”

**Example**

See the example in “GETIMAGE, GETIMAGE_W”.

---

**INCHARQQ**

**QuickWin Function:** Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```plaintext
result = INCHARQQ()
```

**Results:**

The result type is INTEGER(2). The result is the ASCII key code.

The keystroke is read from the child window that currently has the focus. You must call INCHARQQ before the keystroke is made (INCHARQQ does not read the keyboard buffer). This function does not echo its input. For function keys, INCHARQQ returns 0xE0 as the upper 8 bits, and the ASCII code as the lower 8 bits.

For direction keys, INCHARQQ returns 0xF0 as the upper 8 bits, and the ASCII code as the lower 8 bits. To allow direction keys to be read, you must use the PASSDIRKEYSQQ function. The escape characters (the upper 8 bits) are different from those of GETCHARQQ. Note that console applications do not need, and cannot use PASSDIRKEYSQQ.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**Example**

```plaintext
use IFQWIN
```
integer*4 res
integer*2 exchar
character*1 ch, ch1

Print *,"Type X to exit, S to scroll, D to pass Direction keys"
123 continue
exchar = incharqq()
! check for escapes
! 0xE0 0x?? is a function key
! 0xF0 0x?? is a direction key
ch = char(rshift(exchar,8) .and. Z'00FF')
ch1= char(exchar .and. Z'00FF')
if (ichar(ch) .eq. 224) then
  print *,"function key = ",ichar(ch), " ",ichar(ch1)," ",ch1
  goto 123
endif
if (ichar(ch) .eq. 240) then
  print *,"direction key = ",ichar(ch), " ",ichar(ch1)," ",ch1
  goto 123
endif
print *,"other key = ",ichar(ch)," ",ichar(ch1)," ",ch1
if(ch1 .eq. ’S’) then
  res = passdirkeysqq(.false.)
  print *, "Entering Scroll mode"
endif
if(ch1 .eq. ’D’) then
  res = passdirkeysqq(.true.)
  print *, "Entering Direction keys mode"
endif
if(ch1 .ne. ’X’)
  go to 123
end

INITIALIZEFONTS

Graphics Function: Initializes Windows* fonts. This function is only available on Windows* systems.
Module: USE IFQWIN
Syntax

result = INITIALIZEFONTS ()

Results:
The result type is INTEGER(2). The result is the number of fonts initialized.

All fonts on Windows systems become available after a call to INITIALIZEFONTS. Fonts must be initialized with INITIALIZEFONTS before any other font-related library function (such as GETFONTINFO, GETGTEXTEXTENT, SETFONT, OUTGTEXT) can be used. For more information, see "Using Fonts from the Graphics Library" in *Building Applications*.

The font functions affect the output of OUTGTEXT only. They do not affect other Fortran I/O functions (such as WRITE) or graphics output functions (such as OUTTEXT).

For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “SETFONT”, “OUTGTEXT”, “Using QuickWin” in *Building Applications*

Example

! build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
numfonts = INITIALIZEFONTS() WRITE (*,*) numfonts
END

**INITIALSETTINGS**

**QuickWin Function:** Initializes QuickWin. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

result = INITIALSETTINGS ( )

**Results:**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can change the initial appearance of an application’s default frame window and menus by defining an INITIALSETTINGS function. Do not use INITIALSETTINGS to open or size child windows.
If no user-defined INITIALSETTINGS function is supplied, QuickWin calls a predefined INITIALSETTINGS routine to control the default frame window and menu appearance. You do not need to call INITIALSETTINGS if you define it, since it will be called automatically during initialization.

For more information, see "Program Control of Menus" in *Building Applications*.

**Compatibility**

QUICKWIN GRAPHICS WINDOWS LIB

See Also: “APPENDMENUQQ”, “INSERTMENUQQ”, “DELETEMENUQQ”, “SETWSIZEQQ”, "Using QuickWin" in *Building Applications*

### INMAX

**Portability Function:** Returns the maximum positive value for an integer.

**Module:** USE IFPORT

**Syntax**

```fortran
result = INMAX (i)
```

*i* (Input) INTEGER(4).

**Results:**

The result type is INTEGER(4). The result is the maximum 4-byte signed integer value for the argument.

### INQFOCUSQQ

**QuickWin Function:** Determines which window has the focus. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = INQFOCUSQQ (unit)
```

*unit* (Output) INTEGER(4). Unit number of the window that has the I/O focus.

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero. The function fails if the window with the focus is associated with a closed unit.
Unit numbers 0, 5, and 6 refer to the default window only if the program has not specifically opened them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

The window with focus is always in the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**Compatibility**

QUICKWIN GRAPHICS LIB

**See Also:** "FOCUSQQ", "Using QuickWin" in *Building Applications*

---

**INSERTMENUQQ**

**QuickWin Function:** Inserts a menu item into a QuickWin menu and registers its callback routine. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```
result = INSERTMENUQQ (menuID, itemID, flag, text, routine)
```

**menuID**

(Input) INTEGER(4). Identifies the menu in which the item is inserted, starting with 1 as the lefthmost menu.

**itemID**

(Input) INTEGER(4). Identifies the position in the menu where the item is inserted, starting with 0 as the top menu item.

**flag**

(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results section below). The following constants are available:
- $MENUGRAYED - Disables and grays out the menu item.
- $MENUDISABLED - Disables but does not gray out the menu item.
- $MENUENABLED - Enables the menu item.
- $MENUSEPARATOR - Draws a separator bar.
- $MENUCHECKED - Puts a check by the menu item.
- $MENUUNCHECKED - Removes the check by the menu item.

**text**

(Input) Character*(*). Menu item name. Must be a null-terminated C string, for example, words of text’C’.

**routine**

(Input) EXERNAL. Callback subroutine that is called if the menu item is selected. All routines must take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- WINPRINT – Prints the program.
- WINSAVE – Saves the program.
- WINEXIT – Terminates the program.
- WINSELECTTEXT – Selects text from the current window.
- WINSELECTGRAPHICS – Selects graphics from the current window.
- WINSELECTALL – Selects the entire contents of the current window.
- WININPUT – Brings to the top the child window requesting input and makes it the current window.
- WINCOPY – Copies the selected text and/or graphics from the current window to the Clipboard.
- WINPASTE – Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WINCLEARPASTE – Clears the paste buffer.
- WINSIZETOFIT – Sizes output to fit window.
- WINFULLSCREEN – Displays output in full screen.
- WINSTATE – Toggles between pause and resume states of text output.
- WINCASCADE – Cascades active windows.
- WINTILE – Tiles active windows.
- WINARRANGE – Arranges icons.
- WINSTATUS – Enables a status bar.
- WININDEX – Displays the index for QuickWin help.
- WINUSING – Displays information on how to use Help.
• WINABOUT – Displays information about the current QuickWin application.
• NUL – No callback routine.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.

Menus and menu items must be defined in order from left to right and top to bottom. For example, INSERTMENUQQ fails if you try to insert menu item 7 when 5 and 6 are not defined yet. For a top-level menu item, the callback routine is ignored if there are subitems under it.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUENABLED. Some combinations do not make sense, such as $MENUENABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to INSERTMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY (ALT+R in the example) as an alternative to selecting the item with the mouse.

For more information on customizing QuickWin menus, see "Using QuickWin" in Building Applications.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “APPENDMENUQQ”, “DELETEMENUQQ”, “MODIFYMENUFLAGSQ”, “MODIFYMENUROUTINEQ”, “MODIFYMENUSTRINGQ”

Example
! build as a QuickWin App.
USE IFQWIN
LOGICAL(4) status
! insert new item into Menu 5 (Window)
status= INSERTMENUQQ(5, 5, $MENUCHECKED, ’New Item’C, & WINSTATUS)

! insert new menu in position 2
status= INSERTMENUQQ(2, 0, $MENUENABLED, ’New Menu’C, & WINSAVE)

END

INTC

Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.
Module: USE IFPORT

Syntax

\[
\text{result} = \text{INTC} (i)
\]

\(i\)

(Input) INTEGER(4). A value or expression.

Results:

The result type is INTEGER(2). The result is the value of \(i\) with type INTEGER(2). Overflow is ignored.

INTEGERTORGB

QuickWin Subroutine: Converts an RGB color value into its red, green, and blue components. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

\[
\text{CALL INTEGERTORGB} (\text{rgb}, \text{red}, \text{green}, \text{blue})
\]

\(\text{rgb}\)

(Input) INTEGER(4). RGB color value whose red, green, and blue components are to be returned.

\(\text{red}\)

(Output) INTEGER(4). Intensity of the red component of the RGB color value.

\(\text{green}\)

(Output) INTEGER(4). Intensity of the green component of the RGB color value.

\(\text{blue}\)

(Output) INTEGER(4). Intensity of the blue component of the RGB color value.

INTEGERTORGB separates the four-byte RGB color value into the three components as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Compatibility

QUICKWIN GRAPHICS WINDOWS LIB
See Also: “RGBTOINTEGER”, “GETCOLORRGB”, “GETBKCOLORRGB”, “GETPIXELRGB, GETPIXELRGB_W”, “GETPIXELSRGB”, “GETTEXTCOLORRGB”, “Using QuickWin” in Building Applications

Example

! build as a QuickWin App.
USE IFQWIN
INTEGER(4) r, g, b
CALL INTEGERTORGB(2456, r, g, b)
write(*,*) r, g, b
END

IPXFARGC

POSIX Function: Returns the index of the last command-line argument.
Module: USE IFPOSIX
Syntax
    result = IPXFARGC()
Results:
The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.
Compatibility
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
See Also: “PXFGETARG”

IPXFCONST

POSIX Function: Returns the value associated with a constant defined in the C POSIX standard.
Module: USE IFPOSIX
Syntax
    result = IPXFCONST(constname)
constname
(Input) Character. The name of a C POSIX standard constant.
**Results:**
The result type is INTEGER(4). If `constname` corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is –1.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “PXGETARG”, “PXCONST”

---

**IPXFLENTTRIM**

**POSIX Function:** Returns the index of the last non-blank character in an input string.

**Module:** USE IFPOSIX

**Syntax**

```fortran
result = IPXFLENTTRIM (string)
```

**string**
(Input) Character. A character string.

**Results:**
The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument `string`, or zero if all characters in `string` are blank characters.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

---

**IPXFWEIXTSTATUS**

**POSIX Function:** Returns the exit code of a child process. This function is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
result = IPXFWEIXTSTATUS (istat)
```

**istat**
(Input) INTEGER(4). The value of output argument `istat` from PXWAIT or PXWAITPID.

**Results:**
The result type is INTEGER(4). The result is the low-order eight bits of the output argument of PXWAIT or PXWAITPID.
The IPXFWEXITSTATUS function should only be used if PXFWIFEXITED returns TRUE.

See Also: “PXFWAIT”, “PXFWAITPID”, “PXFWIFEXITED”

Example

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
    print *," the child process will be born"
    call PXFFORK(IPID, IERROR)
    call PXFGETPID(IPID_RET,IERROR)
    if(IPID.EQ.0) then
        print *," I am a child process"
        print *," My child's pid is", IPID_RET
        call PXFGETPPID(IPID_RET,IERROR)
        print *," The pid of my parent is",IPID_RET
        print *," Now I have exited with code 0xABCD"
        call PXFEXIT(Z'ABCD')
    else
        print *," I am a parent process"
        print *," My parent pid is ", IPID_RET
        print *," I am creating the process with pid", IPID
        print *," Now I am waiting for the end of the child process"
        call PXFWAIT(ISTAT, IPID_RET, IERROR)
        print *," The child with pid ", IPID_RET," has exited"
        if( PXFWIFEXITED(ISTAT) ) then
            print *, " The child exited normally"
            istat_ret = IPXFWEXITSTATUS(ISTAT)
            print 10," The low byte of the child exit code is", istat_ret
        end if
    end if
10 FORMAT (A,Z)
end program
```

**IPXFWSTOPSIG**

**POSIX Function:** Returns the number of the signal that caused a child process to stop. This function is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX
Syntax

result = IPXFWSTOPSIG (istat)

istat
(Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results:
The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop.
The IPXFWSTOPSIG function should only be used if PXFWIFSTOPPED returns TRUE.

See Also: "PXFWAIT", “PXFWAITPID”, “PXFWIFSTOPPED”

IPXFWTERMSIG

POSIX Function: Returns the number of the signal that caused a child process to terminate. This function is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

result = IPXFWTERMSIG (istat)

istat
(Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results:
The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.
The IPXFWTERMSIG function should only be used if PXFWIFSIGNALED returns TRUE.

See Also: “PXFWAIT”, “PXFWAITPID”, “PXFWIFSIGNALED”

IRAND, IRANDM

Portability Functions: Return random numbers in the range 0 through (2**31)–1, or 0 through (2**15)–1 if called without an argument.

Module: USE IFPORT

Syntax

result = IRAND ([iflag])
result = IRANDM (iflag)
iflag
(Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If iflag is omitted, it is assumed to be 0, and the return range is 0 through (2**15)–1 (inclusive).

Results:
The result type is INTEGER(4). If iflag is 1, the generator is restarted and the first random value is returned. If iflag is 0, the next random number in the sequence is returned. If iflag is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SRAND”, the RANDOM_NUMBER and RANDOM_SEED intrinsic routines in the Language Reference

Example
USE IFPORT
INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND (flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do

IRANGET

Portability Subroutine: Returns the current seed.
Module: USE IFPORT
Syntax
    CALL IRANGET (seed)
seed
(Output) INTEGER(4). The current seed value.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “IRANSET”

IRANSET

Portability Subroutine: Sets the seed for the random number generator.
Module: USE IFPORT
Syntax
    CALL IRANSET (seed)

seed
(Input) INTEGER(4). The reset value for the seed.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “IRANGET”

ISATTY

Portability Function: Checks whether a logical unit number is a terminal.
Module: USE IFPORT
Syntax
    result = ISATTY (lunit)

lunit
(Input) INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.

Results:
The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..

If lunit is out of range or is not connected, zero is returned.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
ITIME

**Portability Subroutine:** Returns the time in numeric form.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL ITIME (array)
```

**array**

(Output) INTEGER(4). A rank one array with three elements used to store numeric time data:
- `array(1)` – the hour
- `array(2)` – the minute
- `array(3)` – the second

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** the DATE_AND_TIME intrinsic procedure in the *Language Reference*

**Example**

```fortran
USE IFPORT
    INTEGER(4) time_array(3)
    CALL ITIME (time_array)
    write(*,10) time_array
    10 format (1X,I2,':',I2,':',I2)
END
```

JABS

**Portability Function:** Returns an absolute value.

**Module:** USE IFPORT

**Syntax**

```fortran
result = JABS (i)
```

**i**

(Input) INTEGER(4). A value.

**Results:**

The result type is INTEGER(4). The value of the result is $|i|$.
JDATEN

Portability Function: Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.

Module: USE IFPORT

Syntax
   result = JDATE ( )

Results:
The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.
The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.

CAUTION. The two-digit year return value may cause problems with the year 2000. Use the DATE_AND_TIME intrinsic subroutine instead (see the Language Reference).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference

Example
   ! Sets julian to today’s julian date
   USE IFPORT
   CHARACTER*8 julian
   julian = JDATE( )

JDATEN4

Portability Function: Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.

Module: USE IFPORT

Syntax
   result = JDATE4 ( )

CAUTION. The two-digit year return value may cause problems with the year 2000. Use the DATE_AND_TIME intrinsic subroutine instead (see the Language Reference).
Results:
The result type is character with length 10. The result is the Julian date, in the form YYYYDDD,
followed by three spaces.
The Julian date is a seven-digit number whose first four digits are the year, and whose final three
digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so
on). For example, the Julian date for February 1, 1999 is 1999032.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference

KILL

Portability Function: Sends a signal to the process given by ID.
Module: USE IFPORT
Syntax
result = KILL (pid, signum)

pid
(Input) INTEGER(4). ID of a process to be signaled.

signum
(Input) INTEGER(4). A signal value. For the definition of signal values, see the “SIGNAL”
function.

Results:
The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error
code. Possible error codes are:
• EINVAL: The signum is not a valid signal number, or PID is not the same as getpid( ) and
  signum does not equal SIGKILL.
• ESRCH: The given PID could not be found.
• EPERM: The current process does not have permission to send a signal to the process given
  by PID.

On Windows* systems, arbitrary signals can be sent only to the calling process (where pid =
getpid( ) ). Other processes can send only the SIGKILL signal (signum = 9), and only if the calling
process has permission.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: "RAISEQQ", "SIGNALQQ"

Example
USE IFPORT
integer(4) id_number, sig_val, istat
id_number=getpid()
ISTAT = KILL (id_number, sig_val)

LCWRQQ

Portability Subroutine: Sets the value of the floating-point processor control word.

Module: USE IFPORT

Syntax
CALL LCWRQQ (controlword)

Controlword
(Input) INTEGER(2). Floating-point processor control word.

LCWRQQ performs the same function as the run-time subroutine SETCONTROLFPQQ and is provided for compatibility.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "SETCONTROLFPQQ"

Example
USE IFPORT
INTEGER(2) control
CALL SCWRQQ(control) ! get control word
! Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC) ! Clear
! control word with inverse of rounding control mask
control = control .OR. FPCW$UP ! Set control word
! to round up
CALL LCWRQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END
LINETO, LINETO_W

**Graphics Function:** Draws a line from the current graphics position up to and including the end point. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```plaintext
result = LINETO (x, y)
result = LINETO_W (wx, wy)
```

- **x, y**
  - (Input) INTEGER(2). Viewport coordinates of end point.
- **wx, wy**
  - (Input) REAL(8). Window coordinates of end point.

**Results:**

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0.

The line is drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

If no error occurs, LINETO sets the current graphics position to the viewport point (x, y), and LINETO_W sets the current graphics position to the window point (wx, wy).

If you use FLOODFILLRGB to fill in a closed figure drawn with LINETO, the figure must be drawn with a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**Compatibility**

| STANDARD GRAPHICS | QUICKWIN GRAPHICS |

---

**NOTE.** The LINETO routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the LineTo routine by including the IFWIN module, you need to specify the routine name as MSFWIN$LineTo. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.
Example
This program draws the figure shown below.

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) xy
CALL MOVETO(INT2(80), INT2(50), xy)
status = LINETO(INT2(240), INT2(150))
status = LINETO(INT2(240), INT2(50))
END

LINETOAR

Graphics Function: Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. This function is only available on Windows® systems.

Module: USE IFQWIN
Syntax
result = LINETOAR (loc(fx), loc(fy), loc(tx) loc(ty), cnt)

fx
(Input) INTEGER(2). From x viewport coordinate array.
fy
(Input) INTEGER(2). From y viewport coordinate array.
tx
(Input) INTEGER(2). To x viewport coordinate array.
ty
(Input) INTEGER(2). To y viewport coordinate array.
**cnt**

(Input) INTEGER(4). Length of each coordinate array; all should be the same size.

**Results:**

The result is of type INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS

**See Also:** "LINETO, LINETO_W", "LINETOAREX", "SETCOLORRGB", "SETLINESTYLE", "SETWRITEMODE", the LOC intrinsic function in the Language Reference

**Example**

```fortran
! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3), fy(3), tx(3), ty(3), result
integer(4) cnt, i
! load the points
do i = 1, 3
    ! from here
    fx(i) = 20 * i
    fy(i) = 10
    ! to there
    tx(i) = 20 * i
    ty(i) = 60
end do
! draw the lines all at once
! 3 white vertical lines in upper left corner
result = LINETOAR(loc(fx), loc(fy), loc(tx), loc(ty), 3)
end
```

**LINETOAREX**

**Graphics Function:** Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. Each line is drawn with the specified graphics color and line style. This function is only available on Windows* systems.

**Module:** USE IFQWIN
Syntax

\[
\text{result} = \text{LINETOAREX}(\text{loc}(fx), \text{loc}(fy), \text{loc}(tx) \text{ loc}(ty), \text{loc}(C), \text{loc}(S), \text{cnt})
\]

- \(fx\) (Input) INTEGER(2). From x viewport coordinate array.
- \(fy\) (Input) INTEGER(2). From y viewport coordinate array.
- \(tx\) (Input) INTEGER(2). To x viewport coordinate array.
- \(ty\) (Input) INTEGER(2). To y viewport coordinate array.
- \(C\) (Input) INTEGER(4). Color array.
- \(S\) (Input) INTEGER(4). Style array.
- \(cnt\) (Input) INTEGER(4). Length of each coordinate array; also the length of the color array and style array. All of the arrays should be the same size.

Results:
The result is of type INTEGER(2). The result is a nonzero value if successful; otherwise, zero.
The lines are drawn using the specified graphics colors and line styles, and with the current write mode. The current write mode is set with SETWRITEMODE.
If the color has the Z'80000000' bit set, the color is an RGB color; otherwise, the color is a palette color.
The styles are as follows from wingdi.h:

- SOLID 0
- DASH 1 /* _._._._ */
- DOT 2 /* _._._._ */
- DASHDOT 3 /* _._._._ */
- DASHDOTDOT 4 /* _._._._ */
- NULL 5

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS
See Also: “LINETO, LINETO_W”, “LINETOAR”, “POLYLINEQQ”, “SETWRITEMODE”, the LOC intrinsic function in the Language Reference

Example

! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3), fy(3), tx(3), ty(3), result
integer(4) C(3), S(3), cnt, i, color

color = Z'000000FF'
! load the points
do i = 1, 3
  S(i) = 0  ! all lines solid
  C(i) = IOR(Z'80000000', color)
  color = color*256 ! pick another of RGB
  if(IAND(color, Z'00FFFFFF').eq.0) color = Z'000000FF'
  !from here
  fx(i) = 20*i
  fy(i) = 10
  !to there
  tx(i) = 20*i
  ty(i) = 60
end do
! draw the lines all at once
! 3 vertical lines in upper left corner, Red, Green, and Blue
result = LINETOAREX(loc(fx), loc(fy), loc(tx), loc(ty), loc(C), loc(S), 3)
end

LNBLNK

Portability Function: Locates the position of the last nonblank character in a string.
Module: USE IFPORT
Syntax
  result = LNBLNK (string)
string
  (Input) Character*. String to be searched. Cannot be an array.
Results:
The result type is INTEGER(4). The result is the index of the last nonblank character in string.

LNBLNK is very similar to the intrinsic function LEN_TRIM, except that string cannot be an array.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: the LEN_TRIM intrinsic function in the Language Reference

Example

USE IFPORT
integer(4) p
p = LNBLNK('GOOD DAY') ! returns 9
p = LNBLNK(' ') ! returns 0

LOADIMAGE, LOADIMAGE_W

Graphics Functions: Read an image from a Windows bitmap file and display it at a specified location. These functions are only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = LOADIMAGE (filename, xcoord, ycoord)
result = LOADIMAGE_W (filename, wxcoord, wycoord)

filename
(Input) Character*(*). Path of the bitmap file.

xcoord, ycoord
(Input) INTEGER(4). Viewport coordinates for upper-left corner of image display.

wxcoord, wycoord
(Input) REAL(8). Window coordinates for upper-left corner of image display.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.
The image is displayed with the colors in the bitmap file. If the color palette in the bitmap file is different from the current system palette, the current palette is discarded and the bitmap’s palette is loaded.

LOADIMAGE specifies the screen placement of the image in viewport coordinates.
LOADIMAGE_W specifies the screen placement of the image in window coordinates.
Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “SAVEIMAGE, SAVEIMAGE_W”

LONG

Portability Function: Converts an INTEGER(2) argument to INTEGER(4) type.
Module: USE IFPORT
Syntax
   result = LONG (int2)
int2
(Input) INTEGER(2). Value to be converted.
Results:
The result type is INTEGER(4). The result is the value of int2 with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to int2.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL  LIB

See Also: the INT and KIND intrinsic functions in the Language Reference

LSTAT

Portability Function: Returns detailed information about a file.
Module: USE IFPORT
Syntax
   result = LSTAT (name, statb)
name
(Input) Character*(*). Name of the file to examine.
statb
(Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See “STAT” for the possible values returned in statb.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see “IERRNO”).
LSTAT returns detailed information about the file named in name. On Linux* and Mac OS* systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link. On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function. The INQUIRE statement also provides information about file properties.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “GETFILEINFOQQ”, “STAT”, “FSTAT” the INQUIRE statement in the Language Reference

Example

USE IFPORT
INTEGER(4) info_array(12), istatus
character*20 file_name
print *, "Enter name of file to examine: 
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
   print *, info_array
else
   print *, 'Error ', istatus
end if

LTIME

Portability Subroutine: Returns the components of the local time zone time in a nine-element array.

Module: USE IFPORT

Syntax

   CALL LTIME (time, array)

   time

   (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.
array
(Output) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from time.

The elements of array are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>array(1)</td>
<td>Seconds (0 - 59)</td>
</tr>
<tr>
<td>array(2)</td>
<td>Minutes (0 - 59)</td>
</tr>
<tr>
<td>array(3)</td>
<td>Hours (0 - 23)</td>
</tr>
<tr>
<td>array(4)</td>
<td>Day of month (1 - 31)</td>
</tr>
<tr>
<td>array(5)</td>
<td>Month (0 - 11)</td>
</tr>
<tr>
<td>array(6)</td>
<td>Years since 1900</td>
</tr>
<tr>
<td>array(7)</td>
<td>Day of week (0 - 6, where 0 is Sunday)</td>
</tr>
<tr>
<td>array(8)</td>
<td>Day of year (1 - 365)</td>
</tr>
<tr>
<td>array(9)</td>
<td>1 if daylight saving time is in effect; otherwise, 0.</td>
</tr>
</tbody>
</table>

CAUTION. This subroutine is not year-2000 compliant, use the DATE_AND_TIME intrinsic subroutine instead (see the Language Reference).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: the DATE_AND_TIME intrinsic procedure in the Language Reference

Example

USE IFPORT
INTEGER(4) input_time, time_array(9)
! find number of seconds since 1/1/70
input_time=TIME()
! convert number of seconds to time array
CALL LTIME (input_time, time_array)
PRINT *, time_array
MAKEDIRQQ

**Portability Function:** Creates a new directory with a specified name.

**Module:** USE IFPORT

**Syntax**

```fortran
result = MAKEDIRQQ (dirname)
```

`dirname`

(Input) Character*(*). Name of directory to be created.

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or backslash (\) as valid delimiters.

If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:

- **ERR$ACCES** - Permission denied. The file’s (or directory’s) permission setting does not allow the specified access.
- **ERR$EXIST** - The directory already exists.
- **ERR$NOENT** - The file or path specified was not found.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "DELDIRQQ", "CHANGEDIRQQ", "GETLASTERRORQQ"

**Example**

```fortran
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ('mynewdir')
IF (result) THEN
  WRITE (*,*) 'New subdirectory successfully created'
ELSE
  WRITE (*,*) 'Failed to create subdirectory'
END IF
END
```
**MBCharLen**

**NLS Function:** Returns the length, in bytes, of the first character in a multibyte-character string. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = MBCharLen (string)
```

**string**

(Input) Character*(*). String containing the character whose length is to be determined. Can contain multibyte characters.

**Results:**

The result type is INTEGER(4). The result is the number of bytes in the first character contained in *string*. The function returns 0 if *string* has no characters (is length 0).

MBCharLen does not test for multibyte character validity.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “MBCurMax”, “MBLead”, “MBLen”, “MBLen_Trim”

---

**MBConvertMBToUnicode**

**NLS Function:** Converts a multibyte-character string from the current codepage to a Unicode string. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = MBConvertMBToUnicode (mbstr, unicodestr [, flags])
```

**mbstr**

(Input) Character*(*). Multibyte codepage string to be converted.

**unicodestr**

(Output) INTEGER(2). Array of integers that is the translation of the input string into Unicode.

**flags**

(Optional; input) INTEGER(4). If specified, modifies the string conversion. If *flags* is omitted, the value NLS$Precomposed is used. Available values (defined in IFNLS.F90) are:

- NLS$Precomposed: Use precomposed characters always. This is the default.
- NLS$Composite: Use composite wide characters always.
• NLS$UseGlyphChars: Use glyph characters instead of control characters.
• NLS$ErrorOnInvalidChars: Returns –1 if an invalid input character is encountered.

The flags NLS$Precomposed and NLS$Composite are mutually exclusive. You can combine NLS$UseGlyphChars with either NLS$Precomposed or NLS$Composite using an inclusive OR (IOR or OR).

Results:
The result type is INTEGER(4). If no error occurs, the result is the number of bytes written to unicodestr (bytes are counted, not characters), or the number of bytes required to hold the output string if unicodestr has zero size. If the unicodestr array is bigger than needed to hold the translation, the extra elements are set to space characters. If unicodestr has zero size, the function returns the number of bytes required to hold the translation and nothing is written to unicodestr.

If an error occurs, one of the following negative values is returned:
• NLS$ErrorInsufficientBuffer: The unicodestr argument is too small, but not zero size so that the needed number of bytes would be returned.
• NLS$ErrorInvalidFlags: The flags argument has an illegal value.
• NLS$ErrorInvalidCharacter: A character with no Unicode translation was encountered in mbstr. This error can occur only if the NLS$InvalidCharsError flag was used in flags.

NOTE. By default, or if flags is set to NLS$Precomposed, the function MBConvertMBToUnicode attempts to translate the multibyte codepage string to a precomposed Unicode string. If a precomposed form does not exist, the function attempts to translate the codepage string to a composite form.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “MBConvertUnicodeToMB”

MBConvertUnicodeToMB

NLS Function: Converts a Unicode string to a multibyte-character string from the current codepage. This function is only available on Windows® systems.

Module: USE IFNLS

Syntax

result = MBConvertUnicodeToMB (unicodestr, mbstr [,flags])
**unicodestr**
( Input ) INTEGER(2). Array of integers holding the Unicode string to be translated.

**mbstr**
( Output ) Character*(*) . Translation of Unicode string into multibyte character string from the current codepage.

**flags**
(Optional; input) INTEGER(4). If specified, argument to modify the string conversion. If flags is omitted, no extra checking of the conversion takes place. Available values (defined in IFNLS.F90) are:

- NLS$CompositeCheck: Convert composite characters to precomposed.
- NLS$SepChars: Generate separate characters.
- NLS$DiscardDns: Discard nonspacing characters.
- NLS$DefaultChars: Replace exceptions with default character.

The last three flags (NLS$SepChars, NLS$DiscardDns, and NLS$DefaultChars) are mutually exclusive and can be used only if NLS$CompositeCheck is set, in which case one (and only one) of them is combined with NLS$CompositeCheck using an inclusive OR (IOR or OR). These flags determine what translation to make when there is no precomposed mapping for a base character/nonspace character combination in the Unicode wide character string. The default (IOR(NLS$CompositeCheck, NLS$SepChars)) is to generate separate characters.

**Results:**
The result type is INTEGER(4). If no error occurs, returns the number of bytes written to mbstr (bytes are counted, not characters), or the number of bytes required to hold the output string if mbstr has zero length. If mbstr is longer than the translation, it is blank-padded. If mbstr is zero length, the function returns the number of bytes required to hold the translation and nothing is written to mbstr.

If an error occurs, one of the following negative values is returned:
- NLS$ErrorInsufficientBuffer: The mbstr argument is too small, but not zero length so that the needed number of bytes is returned.
- NLS$ErrorInvalidFlags: The flags argument has an illegal value.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “MBConvertMBToUnicode”
MBCurMax

**NLS Function:** Returns the longest possible multibyte character length, in bytes, for the current codepage. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = MBCurMax()
```

**Results:**

The result type is INTEGER(4). The result is the longest possible multibyte character, in bytes, for the current codepage.

The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “MBCharLen”

MBINCHARQQ

**NLS Function:** Performs the same function as INCHARQQ except that it can read a single multibyte character at once, and it returns the number of bytes read as well as the character. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = MBINCHARQQ(string)
```

`string`

(Output) CHARACTER(MBLenMax). String containing the read characters, padded with blanks up to the length MBLenMax. The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

**Results:**

The result type is INTEGER(4). The result is the number of characters read.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “INCHARQQ”, “MBCurMax”, “MBCharLen”, “MBLead”
MBINDEX

**NLS Function:** Performs the same function as the INDEX intrinsic function except that the strings manipulated can contain multibyte characters. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = MBINDEX (string, substring [, back])
```

- **string**
  (Input) CHARACTER*(*). String to be searched for the presence of `substring`. Can contain multibyte characters.

- **substring**
  (Input) CHARACTER*(*). Substring whose position within `string` is to be determined. Can contain multibyte characters.

- **back**
  (Optional; input) LOGICAL(4). If specified, determines direction of the search. If `back` is .FALSE. or is omitted, the search starts at the beginning of `string` and moves toward the end. If `back` is .TRUE., the search starts end of `string` and moves toward the beginning.

**Results:**

The result type is INTEGER(4). If `back` is omitted or is .FALSE., returns the leftmost position in `string` that contains the start of `substring`. If `back` is .TRUE., returns the rightmost position in `string` which contains the start of `substring`. If `string` does not contain `substring`, returns 0. If `substring` occurs more than once, returns the starting position of the first occurrence (“first” is determined by the presence and value of `back`).

**Compatibility**

| CONSOLE | STANDARD | GRAPHICS | QUICKWIN | GRAPHICS | WINDOWS | DLL | LIB |

**See Also:** “MBSCAN”, “MBVERIFY”, the INDEX intrinsic function in the Language Reference

MBJISToJMS, MBJMSToJIS

**NLS Functions:** Converts Japan Industry Standard (JIS) characters to Microsoft Kanji (JMS) characters, or converts JMS characters to JIS characters. These functions are only available on Windows* systems.

**Module:** USE IFNLS
Syntax

\[
\text{result} = \text{MBJISToJMS (char)}
\]

\[
\text{result} = \text{MBJMSToJIS (char)}
\]

\[
\text{char}
\]

(Input) CHARACTER(2). JIS or JMS character to be converted.

A JIS character is converted only if the lead and trail bytes are in the hexadecimal range 21 through 7E.

A JMS character is converted only if the lead byte is in the hexadecimal range 81 through 9F or E0 through FC, and the trail byte is in the hexadecimal range 40 through 7E or 80 through FC.

Results:

The result type is character with length 2. MBJISToJMS returns a Microsoft Kanji (Shift JIS or JMS) character. MBJMSToJIS returns a Japan Industry Standard (JIS) character.

Only computers with Japanese installed as one of the available languages can use the MBJISToJMS and MBJMSToJIS conversion functions.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSEnumLocales”, “NLSEnumCodepages”, “NLSGetLocale”, “NLSSetLocale”

MBLead

NLS Function: Determines whether a given character is the lead (first) byte of a multibyte character sequence. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax

\[
\text{result} = \text{MBLead (char)}
\]

\[
\text{char}
\]

(Input) CHARACTER(1). Character to be tested for lead status.

Results:

The result type is LOGICAL(4). The result is .TRUE. if \text{char} is the first character of a multibyte character sequence; otherwise, .FALSE.. MBLead only works stepping forward through a whole multibyte character string. For example:

```
DO i = 1, LEN(str)  ! LEN returns the number of bytes, not the
                     ! number of characters in str
      WRITE(*, 100) MBLead (str(i:i))
```
MBLead is passed only one character at a time and must start on a lead byte and step through a string to establish context for the character. MBLead does not correctly identify a nonlead byte if it is passed only the second byte of a multibyte character because the status of lead byte or trail byte depends on context.

The function MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context. So, MBStrLead can be much slower than MBLead (up to \( n \) times slower, where \( n \) is the length of the string).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “MBStrLead”, “MBCharLen”

---

**MBLen**

**NLS Function:** Returns the number of characters in a multibyte-character string, including trailing blanks. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result = MBLen (string)}
\]

**string**

(Input) CHARACTER*(*) String whose characters are to be counted. Can contain multibyte characters.

**Results:**

The result type is INTEGER(4). The result is the number of characters in \( \text{string} \).

MBLen recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “MBLen_Trim”, “MBStrLead”
MBLen_Trim

**NLS Function:** Returns the number of characters in a multibyte-character string, not including trailing blanks. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result} = \text{MBLen\_Trim}\ (\text{string})
\]

**string**

(Input) Character*(*) String whose characters are to be counted. Can contain multibyte characters.

**Results:**

The result type is INTEGER(4). The result is the number of characters in \text{string} minus any trailing blanks (blanks are bytes containing character 32 (hex 20) in the ASCII collating sequence).

MBLen_Trim recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “**MBLen**, **MBStrLead**”

MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE

**NLS Functions:** Perform the same functions as the LGE, LGT, LLE, and LLT intrinsic functions and the logical operators .EQ. and .NE. except that the strings being compared can include multibyte characters, and optional flags can modify the comparison. These functions are only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\begin{align*}
\text{result} & = \text{MBLGE}\ (\text{string}_a, \text{string}_b, [\text{flags}]) \\
\text{result} & = \text{MBLGT}\ (\text{string}_a, \text{string}_b, [\text{flags}]) \\
\text{result} & = \text{MBLLE}\ (\text{string}_a, \text{string}_b, [\text{flags}]) \\
\text{result} & = \text{MBLLT}\ (\text{string}_a, \text{string}_b, [\text{flags}]) \\
\text{result} & = \text{MBLEQ}\ (\text{string}_a, \text{string}_b, [\text{flags}]) \\
\text{result} & = \text{MBLNE}\ (\text{string}_a, \text{string}_b, [\text{flags}])
\end{align*}
\]

**string**

(Input) Character*(*) Strings to be compared. Can contain multibyte characters.
flags

(Optional; input) INTEGER(4). If specified, determines which character traits to use or ignore when comparing strings. You can combine several flags using an inclusive OR (IOR or OR). There are no illegal combinations of flags, and the functions may be used without flags, in which case all flag options are turned off. The available values (defined in IFNLS.F90) are:

- NLS$MB_IgnoreCase - Ignore case.
- NLS$MB_IgnoreNonspace - Ignore nonspacing characters (this flag removes Japanese accent characters if they exist).
- NLS$MB_IgnoreSymbols - Ignore symbols.
- NLS$MB_IgnoreKanaType - Do not differentiate between Japanese Hiragana and Katakana characters (corresponding Hiragana and Katakana characters will compare as equal).
- NLS$MB_IgnoreWidth - Do not differentiate between a single-byte character and the same character as a double byte.
- NLS$MB_StringSort - Sort all symbols at the beginning, including the apostrophe and hyphen (see the Note below).

Results:

The result type is LOGICAL(4). Comparisons are made using the current locale, not the current codepage. The codepage used is the default for the language/country combination of the current locale.

The results of these functions are as follows:

- MBLGE returns .TRUE. if the strings are equal or string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLGT returns .TRUE. if string_a comes last in the collating sequence; otherwise, .FALSE..
- MBLLE returns .TRUE. if the strings are equal or string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLLT returns .TRUE. if string_a comes first in the collating sequence; otherwise, .FALSE..
- MBLEQ returns .TRUE. if the strings are equal in the collating sequence; otherwise, .FALSE..
- MBLNE returns .TRUE. if the strings are not equal in the collating sequence; otherwise, .FALSE..

If the two strings are of different lengths, they are compared up to the length of the shortest one. If they are equal to that point, then the return value indicates that the longer string is greater.

If flags is invalid, the functions return .FALSE.
If the strings supplied contain Arabic Kashidas, the Kashidas are ignored during the comparison. Therefore, if the two strings are identical except for Kashidas within the strings, the functions return a value indicating they are "equal" in the collation sense, though not necessarily identical.

**NOTE.** When not using the NLS$MB_StringSort flag, the hyphen and apostrophe are special symbols and are treated differently than others. This is to ensure that words like coop and co-op stay together within a list.

All symbols, except the hyphen and apostrophe, sort before any other alphanumeric character. If you specify the NLS$MB_StringSort flag, hyphen and apostrophe sort at the beginning also.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** the LGE, LGT, LLE, and LLT intrinsic functions in the *Language Reference*

**MBNext**

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately following the given position in a multibyte-character string. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```
result = MBNext (string, position)
```

**string**

(Input) Character*(*) String to be searched for the first lead byte or single-byte character after the current position. Can contain multibyte characters.

**position**

(Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of a trail (second) byte of a multibyte character.

**Results:**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in string immediately following the position given in position, or 0 if no following first byte is found in string.
MBPrev

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately preceding the given string position in a multibyte-character string. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result} = \text{MBPrev} (\text{string}, \text{position})
\]

**string**
(Input) Character*(*) String to be searched for the first lead byte or single-byte character before the current position. Can contain multibyte characters.

**position**
(Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or single-byte character. Cannot be the position of the trail (second) byte of a multibyte character.

**Results:**

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in string immediately preceding the position given in position, or 0 if no preceding first byte is found in string.

**Compatibility**

MBSCAN

**NLS Function:** Performs the same function as the SCAN intrinsic function except that the strings manipulated can contain multibyte characters. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result} = \text{MBSCAN} (\text{string}, \text{set}, \text{back})
\]
**MBStrLead**

**NLS Function:** Performs a context-sensitive test to determine whether a given character byte in a string is a multibyte-character lead byte. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result} = \text{MBStrLead} (\text{string}, \text{position})
\]

**String**

(Input) Character*(*). String containing the character byte to be tested for lead status.

**Position**

(Input) INTEGER(4). Position in string of the character byte in the string to be tested.

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if the character byte in position of string is a lead byte; otherwise, .FALSE..

MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context.
MBLead is passed only one character at a time and must start on a lead byte and step through a string one character at a time to establish context for the character. So, MBStrLead can be much slower than MBLead (up to \( n \) times slower, where \( n \) is the length of the string).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "MBLead"

### MBVERIFY

**NLS Function:** Performs the same function as the VERIFY intrinsic function except that the strings manipulated can contain multibyte characters. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[
\text{result} = \text{MBVERIFY}(\text{string}, \text{set}[, \text{back}])
\]

*\text{string}*: (Input) Character*(*). String to be searched for presence of any character not in \( \text{set} \).

*\text{set}*: (Input) Character*(*). Set of characters tested to verify that it includes all the characters in \( \text{string} \).

*\text{back}*: (Optional; input) LOGICAL(4). If specified, determines direction of the search. If \( \text{back} \) is .FALSE. or is omitted, the search starts at the beginning of \( \text{string} \) and moves toward the end. If \( \text{back} \) is .TRUE., the search starts end of \( \text{string} \) and moves toward the beginning.

**Results:**

The result type is INTEGER(4). If \( \text{back} \) is .FALSE. or is omitted, it returns the position of the leftmost character in \( \text{string} \) that is not in \( \text{set} \). If \( \text{back} \) is .TRUE., it returns the rightmost character in \( \text{string} \) that is not in \( \text{set} \). If all the characters in \( \text{string} \) are in \( \text{set} \), it returns 0.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "MBINDEX", "MBSCAN", the VERIFY intrinsic function in the Language Reference

### MESSAGEBOXQQ

**QuickWin Function:** Displays a message box in a QuickWin window. This function is only available on Windows* systems.
Module: USE IFQWIN

Syntax

result = MESSAGEBOXQQ (msg, caption, mtype)

msg

caption

mtype
(Input) INTEGER(4). Symbolic constant that determines the objects (buttons and icons) and properties of the message box. You can combine several constants (defined in IFQWIN.F90) using an inclusive OR (IOR or OR). The symbolic constants and their associated objects or properties are as follows:

- MB$ABORTRETRYIGNORE – The Abort, Retry, and Ignore buttons.
- MB$DEFBUTTON1 – The first button is the default.
- MB$DEFBUTTON2 – The second button is the default.
- MB$DEFBUTTON3 – The third button is the default.
- MB$ICONASTERISK, MB$ICONINFORMATION – Lowercase i in blue circle icon.
- MB$ICONEXCLAMATION – The exclamation-mark icon.
- MB$ICONHAND, MB$ICONSTOP – The stop-sign icon.
- MB$ICONQUESTION – The question-mark icon.
- MB$OK – The OK button.
- MB$OKCANCEL – The OK and Cancel buttons.
- MB$RETRYCANCEL – The Retry and Cancel buttons.
- MB$SYSTEMMODAL – Box is system-modal: all applications are suspended until the user responds.
- MB$YESNO – The Yes and No buttons.
- MB$YESNOCANCEL – The Yes, No, and Cancel buttons.

Results:
The result type is INTEGER(4). The result is zero if memory is not sufficient for displaying the message box. Otherwise, the result is one of the following values, indicating the user’s response to the message box:

- MB$IDABORT – The Abort button was pressed.
- MB$IDCANCEL – The Cancel button was pressed.
- MB$IDIGNORE – The Ignore button was pressed.
• MB$IDNO – The No button was pressed.
• MB$IDOK – The OK button was pressed.
• MB$IDRETRY – The Retry button was pressed.
• MB$IDYES – The Yes button was pressed.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "ABOUTBOXQQ", "SETMESSAGEQQ", "Using QuickWin" in Building Applications

Example
! Build as QuickWin app
USE IFQWIN
message = MESSAGEBOXQQ('Do you want to continue?','Matrix' &
  'Matrix' &
  MB$ICONQUESTION.OR.MB$YESNO.OR.MB$DEFBUTTON1)
END

MODIFYMENUFLAGSQQ

QuickWin Function: Modifies a menu item’s state. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax
result = MODIFYMENUFLAGSQQ (menuID, itemID, flag)

menuID
(Input) INTEGER(4). Identifies the menu containing the item whose state is to be modified, starting with 1 as the leftmost menu.

itemID
(Input) INTEGER(4). Identifies the menu item whose state is to be modified, starting with 0 as the top item.

flag
(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:
• $MENUGRAYED – Disables and grays out the menu item.
• $MENUDISABLED – Disables but does not gray out the menu item.
• $MENUENABLED – Enables the menu item.
• $MENUSEPARATOR – Draws a separator bar.
• $MENUCHECKED – Puts a check by the menu item.
• $MENUUNCHECKED – Removes the check by the menu item.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
The constants available for flags can be combined with an inclusive OR where reasonable, for
example $MENUCHECKED .OR. $MENUEND. Some combinations do not make sense,
such as $MENUEND and $MENUDISABLED, and lead to undefined behavior.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “APPENDMENUQQ”, “DELETEMENUQQ”, “INSERTMENUQQ”,
“MODIFYMENUROUTINEQQ”, “MODIFYMENUSTRINGQQ”, “Using QuickWin” in
Building Applications

Example
USE IFQWIN
LOGICAL(4) result
CHARACTER(20) str

! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'C
result = APPENDMENUQQ(1, $MENUEND, str, WINSTATUS)
! Gray out and disable the first two menu items in the
! first (FILE) menu
result = MODIFYMENURFLAGSQQ (1, 1, $MENUGRAYED)
result = MODIFYMENURFLAGSQQ (1, 2, $MENUGRAYED)
END

MODIFYMENUROUTINEQQ

QuickWin Function: Changes a menu item’s callback routine. This function is only available on
Windows® systems.

Module: USE IFQWIN

Syntax
result = MODIFYMENUROUTINEQQ (menuIdD, itemID, routine)
menuID
(Input) INTEGER(4). Identifies the menu that contains the item whose callback routine is to be changed, starting with 1 as the leftmost menu.

itemID
(Input) INTEGER(4). Identifies the menu item whose callback routine is to be changed, starting with 0 as the top item.

routine
(Input) EXTERNAL. Callback subroutine called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- WINPRINT – Prints the program.
- WINSAVE – Saves the program.
- WINEXIT – Terminates the program.
- WINSELECTTEXT – Selects text from the current window.
- WINSELECTGRAPHICS – Selects graphics from the current window.
- WINSELECTALL – Selects the entire contents of the current window.
- WININPUT – Brings to the top the child window requesting input and makes it the current window.
- WINCOPY – Copies the selected text and/or graphics from the current window to the Clipboard.
- WINPASTE – Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WINCLEARPASTE – Clears the paste buffer.
- WINSIZETOFIT – Sizes output to fit window.
- WINFULLSCREEN – Displays output in full screen.
- WINSTATE – Toggles between pause and resume states of text output.
- WINCASCADE – Cascades active windows.
- WINTILE – Tiles active windows.
- WINARRANGE – Arranges icons.
- WINSTATUS – Enables a status bar.
- WININDEX – Displays the index for QuickWin help.
- WINUSING – Displays information on how to use Help.
- WINABOUT – Displays information about the current QuickWin application.
- NUL – No callback routine.
Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “APPENDMENUQ”, “DELETEMENUQ”, “INSERTMENUQ”, “MODIFYMENUFLAGSQ”, “MODIFYMENUSTRINGQ”. "Using QuickWin" in Building Applications

MODIFYMENUSTRINGQ

QuickWin Function: Changes a menu item’s text string. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax
result = MODIFYMENUSTRINGQ (menuID, itemID, text)

menuID
(Input) INTEGER(4). Identifies the menu containing the item whose text string is to be changed, starting with 1 as the leftmost item.

itemID
(Input) INTEGER(4). Identifies the menu item whose text string is to be changed, starting with 0 as the top menu item.

text
(Input) Character*(*) Menu item name. Must be a null-terminated C string. For example, words of text'C.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
You can add access keys in your text strings by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, use "P&rint"C as text.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “APPENDMENUQ”, “DELETEMENUQ”, “INSERTMENUQ”, “SETMESSAGEQ”, “MODIFYMENUFLAGSQ”, “MODIFYMENUROUTINEQ”. "Using QuickWin" in Building Applications
Example

USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str

! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'\nresult = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Change the name of the first item in the first menu
str = '&Browse'\nresult = MODIFYMENUSTRINGQQ (1, 1, str)

END

MOVETO, MOVETO_W

Graphics Subroutines: Move the current graphics position to a specified point. No drawing occurs. These subroutines are only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL MOVETO (x, y, t)
CALL MOVETO_W (wx, wy, wt)

x, y
(Input) INTEGER(2). Viewport coordinates of the new graphics position.

(t)
(Output) Derived type xycoord. Viewport coordinates of the previous graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

TYPE xycoord
    INTEGER(2) xcoord ! x coordinate
    INTEGER(2) ycoord ! y coordinate
END TYPE xycoord

wx, wy
(Input) REAL(8). Window coordinates of the new graphics position.

(wt)
(Output) Derived type wxycoord. Window coordinates of the previous graphics position. The derived type wxycoord is defined in IFQWIN.F90 as follows:
TYPE wxycoord
   REAL(8) wx  ! x window coordinate
   REAL(8) wy  ! y window coordinate
END TYPE wxycoord

MOVETO sets the current graphics position to the viewport coordinate \((x, y)\). MOVETO_W sets the current graphics position to the window coordinate \((wx, wy)\).

MOVETO and MOVETO_W assign the coordinates of the previous position to \(t\) and \(wt\), respectively.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “GETCURRENTPOSITION, GETCURRENTPOSITION_W”, “LINETO, LINETO_W”, “OUTGTEXT”

**Example**

! Build as QuickWin or Standard Graphics ap.

USE IFQWIN

INTEGER(2) status, x, y

INTEGER(4) result

TYPE (xycoord) xy

RESULT = SETCOLORRGB(Z'FF0000') ! blue

x = 60

! Draw a series of lines

DO y = 50, 92, 3
   CALL MOVETO(x, y, xy)
   status = LINETO(INT2(x + 20), y)
END DO

END

**NLS EnumCodepages**

**NLS Function:** Returns an array containing the codepages supported by the system, with each array element describing one valid codepage. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

\[ ptr => \text{NLSEnumCodepages}() \]
Results:
The result is a pointer to an array of codepages, with each element describing one supported codepage.

NOTE. After use, the pointer returned by NLSEnumCodepages should be deallocated with the DEALLOCATE statement.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “NLSEnumLocales”, the DEALLOCATE statement in the Language Reference

NLSEnumLocales

NLS Function: Returns an array containing the language and country combinations supported by the system, in which each array element describes one valid combination. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax

gtr => NLSEnumLocales ( )

Results:
The result is a pointer to an array of locales, in which each array element describes one supported language and country combination. Each element has the following structure:

TYPE NLS$EnumLocale
  CHARACTER*(NLS$MaxLanguageLen) Language
  CHARACTER*(NLS$MaxCountryLen) Country
  INTEGER(4) DefaultWindowsCodepage
  INTEGER(4) DefaultConsoleCodepage
END TYPE
If the application is a Windows or QuickWin application, NLSSDefaultWindowsCodepage is the codepage used by default for the given language and country combination. If the application is a console application, NLSSDefaultConsoleCodepage is the codepage used by default for the given language and country combination.

NOTE. After use, the pointer returned by NLSEnumLocales should be deallocated with the DEALLOCATE statement.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSEnumCodepages”, the DEALLOCATE statement in the Language Reference

NLSFormatCurrency

NLS Function: Returns a correctly formatted currency string for the current locale. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax

result = NLSFormatCurrency (outstr, instr [, flags ])

outstr
(Output) Character*(*) . String containing the correctly formatted currency for the current locale. If outstr is longer than the formatted currency, it is blank-padded.

instr
(Input) Character*(*) . Number string to be formatted. Can contain only the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

flags
(Optional; input) INTEGER(4) . If specified, modifies the currency conversion. If you omit flags, the flag NLSSNormal is used. Available values (defined in IFNLS.F90) are:

• NLSSNormal – No special formatting
• NLSSNoUserOverride – Do not use user overrides

Results:
The result type is INTEGER(4). The result is the number of characters written to `outstr` (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer – `outstr` buffer is too small
- NLS$ErrorInvalidFlags – `flags` has an illegal value
- NLS$ErrorInvalidInput – `instr` has an illegal value

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSFormatNumber”, “NLSFormatDate”, “NLSFormatTime”

**Example**

```fortran
USE IFNLS

CHARACTER(40) str
INTEGER(4) i

i = NLSFormatCurrency(str, "1.23")
print *, str ! prints $1.23
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints $1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatCurrency(str, "1.23")
print *, str ! prints 1 Pts
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints 1.000.001 Pts
```

**NLSFormatDate**

**NLS Function:** Returns a correctly formatted string containing the date for the current locale. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = NLSFormatDate (outstr [, intime ] [, flags])
```

- **outstr**
  (Output) Character*(*). String containing the correctly formatted date for the current locale. If `outstr` is longer than the formatted date, it is blank-padded.

- **intime**
(Optional; input) INTEGER(4). If specified, date to be formatted for the current locale. Must be an integer date such as the packed time created with PACKTIMEQQ. If you omit inTime, the current system date is formatted and returned in outStr.

flags
(Optional; input) INTEGER(4). If specified, modifies the date conversion. If you omit flags, the flag NLSS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLSS$Normal – No special formatting
- NLSS$NoUserOverride – Do not use user overrides
- NLSS$UseAltCalendar – Use the locale’s alternate calendar
- NLSS$LongDate – Use local long date format
- NLSS$ShortDate – Use local short date format

Results:
The result type is INTEGER(4). The result is the number of characters written to outStr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLSS$ErrorInsufficientBuffer – outStr buffer is too small
- NLSS$ErrorInvalidFlags – flags has an illegal value
- NLSS$ErrorInvalidInput – inTime has an illegal value

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSFormatTime”, “NLSFormatCurrency”, “NLSFormatNumber”

Example
USE IFNLS
INTEGER(4) i
CHARACTER(40) str
i = NLSFORMATDATE(str, NLSS$NORMAL) ! 8/1/99
i = NLSFORMATDATE(str, NLSS$USEALTCALENDAR) ! 8/1/99
i = NLSFORMATDATE(str, NLSS$LONGDATE) ! Monday, August 1, 1999
i = NLSFORMATDATE(str, NLSS$SHORTDATE) ! 8/1/99
END

NLSFormatNumber

NLS Function: Returns a correctly formatted number string for the current locale. This function is only available on Windows® systems.
Module: USE IFNLS

Syntax

\[
\text{result} = \text{NLSFormatNumber}(\text{outstr}, \text{instr}, [\text{flags}])
\]

\text{outstr}

(Output) Character*(*). String containing the correctly formatted number for the current locale. If \text{outstr} is longer than the formatted number, it is blank-padded.

\text{instr}

(Input) Character*(*). Number string to be formatted. Can only contain the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

\text{flags}

(Optional; input) INTEGER(4). If specified, modifies the number conversion. If you omit \text{flags}, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal – No special formatting
- NLS$NoUserOverride – Do not use user overrides

Results:

The result type is INTEGER(4). The result is the number of characters written to \text{outstr} (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer – \text{outstr} buffer is too small
- NLS$ErrorInvalidFlags – \text{flags} has an illegal value
- NLS$ErrorInvalidInput – \text{instr} has an illegal value

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSFormatTime”, “NLSFormatCurrency”, “NLSFormatDate”

Example

USE IFNLS
CHARACTER(40) \text{str}
INTEGER(4) \text{i}
\text{i} = NLSFormatNumber(\text{str}, "1.23")
print *, \text{str} ! prints 1.23
\text{i} = NLSFormatNumber(\text{str}, "1000000.99")
print *, \text{str} ! prints 1,000,000.99
\text{i} = NLSSetLocale("Spanish", "Spain")
i = NLSFormatNumber(str, "1.23")
print *, str                    ! prints 1,23
i = NLSFormatNumber(str, "1000000.99")
print *, str                    ! prints 1.000.000,99

NLSFormatTime

NLS Function: Returns a correctly formatted string containing the time for the current locale. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax

result = NLSFormatTime (outstr [, intime ] [, flags ])

outstr
(Output) Character*(*). String containing the correctly formatted time for the current locale. If outstr is longer than the formatted time, it is blank-padded.

intime
(Optional; input) INTEGER(4). If specified, time to be formatted for the current locale. Must be an integer time such as the packed time created with PACKTIMEQQ. If you omit intime, the current system time is formatted and returned in outstr.

flags
(Optional; input) INTEGER(4). If specified, modifies the time conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:
- NLS$Normal – No special formatting
- NLS$NoUserOverride – Do not use user overrides
- NLS$NoMinutesOrSeconds – Do not return minutes or seconds
- NLS$NoSeconds – Do not return seconds
- NLS$NoTimeMarker – Do not add a time marker string
- NLS$Force24HourFormat – Return string in 24 hour format

Results:
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:
- NLS$ErrorInsufficientBuffer – outstr buffer is too small
- NLS$ErrorInvalidFlags – flags has an illegal value
- NLS$ErrorInvalidInput – intime has an illegal value
Descriptions of the Library Routines

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSFormatCurrency”, “NLSFormatDate”, “NLSFormatNumber”

Example
USE IFNLS
INTEGER(4) i
CHARACTER(20) str
i = NLSFORMATTIME(str, NLS$NORMAL) ! 11:38:28 PM
i = NLSFORMATTIME(str, NLS$NOMINUTESORSECONDS) ! 11 PM
i = NLSFORMATTIME(str, NLS$NOTIMEMARKER) ! 11:38:28 PM
i = NLSFORMATTIME(str, IOR(NLS$FORCE24HOURFORMAT, &
& NLS$NOSECONDS)) ! 23:38 PM
END

NLSGetEnvironmentCodepage

NLS Function: Returns the codepage number for the system (Window) codepage or the console codepage. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax
result = NLSGetEnvironmentCodepage (flags)

flags
(Input) INTEGER(4). Tells the function which codepage number to return. Available values (defined in IFNLS.F90) are:
• NLS$ConsoleEnvironmentCodepage – Gets the codepage for the console
• NLS$WindowsEnvironmentCodepage – Gets the current Windows codepage

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, it returns one of the following error codes:
• NLS$ErrorInvalidFlags – flags has an illegal value
• NLS$ErrorNoConsole – There is no console associated with the given application; so, operations with the console codepage are not possible

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSSetEnvironmentCodepage”
NLSGetLocale

**NLS Subroutine:** Returns the current language, country, or codepage. This subroutine is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
CALL NLSGetLocale ([language] [, country] [, codepage])
```

- **language**
  - (Optional; output) Character*(*). Current language.
- **country**
  - (Optional; output) Character*(*). Current country.
- **codepage**
  - (Optional; output) INTEGER(4). Current codepage.

NLSGetLocale returns a valid codepage in `codepage`. It does not return one of the NLSS... symbolic constants that can be used with NLSSetLocale.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "NLSSetLocale"

**Example**

```fortran
USE IFNLS
CHARACTER(50) cntry, lang
INTEGER(4)    code
CALL NLSGetLocale (lang, cntry, code) ! get all three
CALL NLSGetLocale (CODEPAGE = code) ! get the codepage
CALL NLSGetLocale (COUNTRY=cntry, CODEPAGE=code) ! get country and codepage
```

NLSGetLocaleInfo

**NLS Function:** Returns information about the current locale. This function is only available on Windows* systems.

**Module:** USE IFNLS

**Syntax**

```fortran
result = NLSGetLocaleInfo (type, outstr)
```

---

2-228
type
(Input) INTEGER(4). NLS parameter requested. A list of parameter names is given in the Table 2-1.

outstr
(Output) Character*(*). Parameter setting for the current locale. All parameter settings placed in outstr are character strings, even numbers. If a parameter setting is numeric, the ASCII representation of the number is used. If the requested parameter is a date or time string, an explanation of how to interpret the format in outstr is given in “NLS Date and Time Format (W*32, W*64)”.

Results:
The result type is INTEGER(4). The result is the number of characters written to outstr if successful, or if outstr has 0 length, the number of characters required to hold the requested information. Otherwise, the result is one of the following error codes (defined in IFNLS.F90):

• NLS$ErrorInvalidLIType – The given type is invalid
• NLS$ErrorInsufficientBuffer – The outstr buffer was too small, but was not 0 (so that the needed size would be returned)

The NLS$LI parameters are used for the argument and select the locale information returned by NLSGetLocaleInfo in outstr. You can perform an inclusive OR with NLS$NoUserOverride and any NLS$LI parameter. This causes NLSGetLocaleInfo to bypass any user overrides and always return the system default value.

Table 2-1 lists and briefly describes the NLS$LI parameters.

Table 2-1 NLS LocaleInfo Parameters (W*32, W*64)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NLS$LI_ILANGUAGE</td>
<td>An ID indicating the language.</td>
</tr>
<tr>
<td>NLS$LI_SLANGUAGE</td>
<td>The full localized name of the language.</td>
</tr>
<tr>
<td>NLS$LI_SENGLANGUAGE</td>
<td>The full English name of the language from the ISO Standard 639. This will always be restricted to characters that map into the ASCII 127 character subset.</td>
</tr>
<tr>
<td>NLS$LI_SABBREVLANGNAME</td>
<td>The abbreviated name of the language, created by taking the 2-letter language abbreviation as found in ISO Standard 639 and adding a third letter as appropriate to indicate the sublanguage.</td>
</tr>
<tr>
<td>NLS$LI_SNATIVELANGNAME</td>
<td>The native name of the language.</td>

</tbody>
</table>

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**NLSSetEnvironmentCodepage**

**NLS Function:** Sets the codepage for the current console. The specified codepage affects the current console program and any other programs launched from the same console. It does not affect other open consoles or any consoles opened later. This function is only available on Windows systems.
Module: USE IFNLS

Syntax

\[
\text{result} = \text{NLSSetEnvironmentCodepage}(\text{codepage}, \text{flags})
\]

codepage

(Input) INTEGER(4). Number of the codepage to set as the console codepage.

flags

(Input) INTEGER(4). Must be set to NLS$ConsoleEnvironmentCodepage.

Results:

The result type is INTEGER(4). The result is zero if successful. Otherwise, returns one of the following error codes (defined in IFNLS.F90):

- NLS$ErrorInvalidCodepage – codepage is invalid or not installed on the system
- NLS$ErrorInvalidFlags – flags is not valid
- NLS$ErrorNoConsole – There is no console associated with the given application; so operations, with the console codepage are not possible

The flags argument must be NLS$ConsoleEnvironmentCodepage; it cannot be NLS$WindowsEnvironmentCodepage. NLSSetEnvironmentCodepage does not affect the Windows* codepage.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSGetEnvironmentCodepage”

NLSSetLocale

NLS Function: Sets the current language, country, or codepage. This function is only available on Windows* systems.

Module: USE IFNLS

Syntax

\[
\text{result} = \text{NLSSetLocale}(\text{language} [, \text{country}] [, \text{codepage}])
\]

language

(Input) Character*(*). One of the languages supported by the Windows* NLS APIs.

country

(Optional; input) Character*(*). If specified, characterizes the language further. If omitted, the default country for the language is set.
codepage
(Optional; input) INTEGER(4). If specified, codepage to use for all character-oriented NLS functions. Can be any valid supported codepage or one of the following predefined values (defined in IFNLS.F90):

- NLS$CurrentCodepage – The codepage is not changed. Only the language and country settings are altered by the function.
- NLS$ConsoleEnvironmentCodepage – The codepage is changed to the default environment codepage currently in effect for console programs.
- NLS$ConsoleLanguageCodepage – The codepage is changed to the default console codepage for the language and country combination specified.
- NLS$WindowsEnvironmentCodepage – The codepage is changed to the default environment codepage currently in effect for Windows programs.
- NLS$WindowsLanguageCodepage – The codepage is changed to the default Windows* codepage for the language and country combination specified.

If you omit codepage, it defaults to NLS$WindowsLanguageCodepage. At program startup, NLS$WindowsEnvironmentCodepage is used to set the codepage.

Results:
The result type is INTEGER(4). The result is zero if successful. Otherwise, one of the following error codes (defined in IFNLS.F90) may be returned:

- NLS$ErrorInvalidLanguage – language is invalid or not supported
- NLS$ErrorInvalidCountry – country is invalid or is not valid with the language specified
- NLS$ErrorInvalidCodepage – codepage is invalid or not installed on the system

NOTE. NLSSetLocale works on installed locales only. Windows systems support many locales, but they must be installed through the system Control Panel/International menu.

When doing mixed-language programming with Fortran and C, calling NLSSetLocale with a codepage other than the default environment Windows codepage causes the codepage in the C run-time library to change by calling C’s setmbcp( ) routine with the new codepage. Conversely, changing the C run-time library codepage does not change the codepage in the Fortran NLS library.

Calling NLSSetLocale has no effect on the locale used by C programs. The locale set with C’s setlocale( ) routine is independent of NLSSetLocale.
Calling NLSSetLocale with the default environment console codepage, NLSConsoleEnvironmentCodepage, causes an implicit call to the Windows API SetFileApisToOEM(). Calling NLSSetLocale with any other codepage causes a call to SetFileApisToANSI().

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “NLSGetLocale”

---

**OUTGTEXT**

**Graphics Subroutine:** In graphics mode, sends a string of text to the screen, including any trailing blanks. This subroutine is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```call outgtext (text)```

**text**

(Input) Character*(*). String to be displayed.

Text output begins at the current graphics position, using the current font set with SETFONT and the current color set with SETCOLORRGB or SETCOLOR. No formatting is provided. After it outputs the text, OUTGTEXT updates the current graphics position.

Before you call OUTGTEXT, you must call the INITIALIZEFONTS function.

Because OUTGTEXT is a graphics function, the color of text is affected by the SETCOLORRGB function, not by SETTEXTCOLORRGB.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETFONTINFO”, “GETGTEXTEXTENT”, “INITIALIZEFONTS”, “MOVETO”, “MOVETO_W”, “SETCOLORRGB”, “SETFONT”, “SETGTEXTROTATION”

**Example**

```!
! build as a QuickWin App.
USE IFQWIN
INTEGER(2) result
INTEGER(4) i
TYPE (xycoord) xys
result = INITIALIZEFONTS()
result = SETFONT('t''Arial''h18w10pvib')```
do i=1,6
   CALL MOVETO(INT2(0),INT2(30*(i-1)),xys)
   grstat=SETCOLOR(INT2(i))
   CALL OUTGTEXT('This should be ')
   SELECT CASE (i)
      CASE (1)
         CALL OUTGTEXT('Blue')
      CASE (2)
         CALL OUTGTEXT('Green')
      CASE (3)
         CALL OUTGTEXT('Cyan')
      CASE (4)
         CALL OUTGTEXT('Red')
      CASE (5)
         CALL OUTGTEXT('Magenta')
      CASE (6)
         CALL OUTGTEXT('Orange')
   END SELECT
end do
END

OUTTEXT

Graphics Subroutine: In text or graphics mode, sends a string of text to the screen, including any trailing blanks. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax
   CALL OUTTEXT (text)

text
   (Input) Character*(*). String to be displayed.

Text output begins at the current text position in the color set with SETTEXTCOLORRGB or SETTEXTCOLOR. No formatting is provided. After it outputs the text, OUTTEXT updates the current text position.

To output text using special fonts, you must use the OUTGTEXT subroutine.

Compatibility
   STANDARD GRAPHICS   QUICKWIN GRAPHICS LIB
See Also: "OUTGTEXT", "SETTEXTPOSITION", "SETTEXTCOLORRGB", the WRITE statement in the Language Reference

Example
USE IFQWIN
INTEGER(2) oldcolor
TYPE (rccoord) rc

CALL CLEARSCREEN($GCLEARSCREEN)
CALL SETTEXTPOSITION (INT2(1), INT2(5), rc)
oldcolor = SETTEXTCOLOR(INT2(4))
CALL OUTTEXT ('Hello, everyone')
END

PACKTIMEQQ

Portability Subroutine: Packs time and date values.
Module: USE IFPORT
Syntax
   CALL PACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

   timedate
   (Output) INTEGER(4). Packed time and date information.

   iyr
   (Input) INTEGER(2). Year (xxxx AD).

   imon
   (Input) INTEGER(2). Month (1 – 12).

   iday
   (Input) INTEGER(2). Day (1 – 31)

   ihr
   (Input) INTEGER(2). Hour (0 – 23)

   imin
   (Input) INTEGER(2). Minute (0 – 59)

   isec
   (Input) INTEGER(2). Second (0 – 59)
The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

**Compatibility**
CONSOLE  STANDARD  GRAPHICS  QUICKWIN  GRAPHICS  DLL  LIB

**See Also:** "UNPACKTIMEQQ", "SETFILETIMEQQ", "GETFILEINFOQQ", "TIMEF"

**Example**
USE IFPORT
INTEGER(2) year, month, day, hour, minute, second, &
       hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour, &
                  minute, second)
END

**PASSDIRKEYSQQ**

**QuickWin Function:** Determines the behavior of direction and page keys in a QuickWin application. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

\[
\text{result} = \text{PASSDIRKEYSQQ} (\text{val})
\]

**val**

(Input) INTEGER(4) or LOGICAL(4).

A value of .TRUE. causes direction and page keys to be input as normal characters (the PassDirKeys flag is turned on). A value of .FALSE. causes direction and page keys to be used for scrolling.

The following constants, defined in IFQWIN.F90, can be used as integer arguments:

* PASS_DIR_FALSE – Turns off any special handling of direction keys. They are not passed to the program by GETCHARQQ.
* PASS_DIR_TRUE – Turns on special handling of direction keys. That is, they are passed to the program by GETCHARQQ.
• **PASS_DIR_INSDEL** – INSERT and DELETE are also passed to the program by **GETCHARQQ**

• **PASS_DIR_CNTRLC** – Only needed for a QuickWin application, but harmless if used with a Standard Graphics application that already passes CTRL+C.

  This value allows CTRL+C to be passed to a QuickWin program by **GETCHARQQ** if the following is true: the program must have removed the File menu EXIT item by using **DELETEMENUUQQ**.

  This value also passes direction keys and INSERT and DELETE.

**Results:**

The return value indicates the previous setting of the PassDirKeys flag.

The return data type is the same as the data type of `val`; that is, either INTEGER(4) or LOGICAL(4).

When the PassDirKeys flag is turned on, the mouse must be used for scrolling since the direction and page keys are treated as normal input characters.

The **PASSDIRKEYSQQ** function is meant to be used primarily with the **GETCHARQQ** and **INCHARQQ** functions. Do not use normal input statements (such as **READ**) with the PassDirKeys flag turned on, unless your program is prepared to interpret direction and page keys.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “**GETCHARQQ**”, “**INCHARQQ**”

**Examples**

```fortran
use IFQWIN
logical*4 res
character*1 ch, ch1
Print *,"Type X to exit, S to scroll, D to pass Direction keys"
123 continue
ch = getcharqq( )
! check for escapes
! 0x00 0x?? is a function key
! 0xE0 0x?? is a direction key
if (ichar(ch) .eq. 0) then
    ch1 = getcharqq()
    print *,"function key follows escape = ",ichar(ch), " ",ichar(ch1)," ",ch1
go to 123
else if (ichar(ch) .eq. 224) then
    ch1 = getcharqq()
```

---

2-241
print *,"direction key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
goto 123
else
print *,ichar(ch)," ",ch 
if(ch .eq. 'S') then 
   res = passdirkeysqq(.false.)
   print *, "Entering Scroll mode ",res
endif
if(ch .eq. 'D') then
   res = passdirkeysqq(.true.)
   print *, "Entering Direction keys mode ",res
endif
if(ch .ne. 'X') go to 123
endif
diffend

The following example uses an integer constant as an argument to PASSDIRKEYSQQ:
c=======================================================================
c

c dirkeys4.for
c

c=======================================================================
c
Compile/Load Input Line for Standard Graphics Full Screen Window
c
ifort /libs:qwins dirkeys4.for

c Compile/Load Input Line for QuickWin Graphics

c ifort /libs:qwin dirkeys4.for

c Program to illustrate how to get almost every character
c from the keyboard in QuickWin or Standard Graphics mode.
c Comment out the delete-menu line for Standard Graphics mode.
c
If you are doing a standard graphics application,
c control C will come in as a Z’03’ without further
c effort.
In a QuickWin application, the File menu Exit item must be deleted, and PassDirKeysQQ called with PASS_DIR_CNTRL.C to get control C.

```
use IFQWIN
integer(4) status
character*1 key1,key2,ch1
write(*,*) 'Initializing'

c-----don't do this for a Standard Grapics application
status = deletemenuqq(1,3) ! stop QuickWin from getting control C

c-----set up to pass all keys to window including control c.
status  = passdirkeysqq(PASS_DIR_CNTRL)

c
read and print characters

c
key1 = getcharqq()

c-----first check for control+c
if(ichar(key1) .eq. 3) then
  write(*,*) 'Control C Received'
  write(*,*) "Really want to quit?"
  write(*,*) "Type Y <cr> to exit, or any other char <cr> to continue."
  read(*,*) ch1
  if(ch1.eq."y" .or. ch1.eq."Y") goto 30
  goto 10
endif
if(ichar(key1).eq.0) then ! function key?
  key2 = getcharqq()
  write(*,15) ichar(key1),ichar(key2),key2
  15 format(1x,2i12,1x,a1,' function key')
else
  if(ichar(key1).eq.224) then ! direction key?
    key2 = getcharqq()
```

2-243
write(*,16) ichar(key1),ichar(key2),key2
16 format(1x,2i12,1x,a1,' direction key')
else
write(*,20) key1,ichar(key1)  ! normal key
20 format(1x,a1,i11)
endif
endif
go to 10
30 stop
end

PEEKCHARQQ

Run-time Function: Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.
Module: USE IFCORE
Syntax
    result = PEEKCHARQQ ( )
Results:
The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..
To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ to .FALSE..
Compatibility
CONSOLE   DLL   LIB
See Also: “GETCHARQQ”, “GETSTRQQ”, “FGETC”, “GETC”
Example
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
    WRITE(*,*) ' Press any key'
    pressed = PEEKCHARQQ ( )
PIE, PIE_W

**Graphics Functions:** Draw a pie-shaped wedge in the current graphics color. These functions are only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```
result = PIE (i, x1, y1, x2, y2, x3, y3, x4, y4)
result = PIE_W (i, wx1, wy1, wx2, wy2, wx3, wy3, wx4, wy4)
```
i
(Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in IFQWIN.F90):
• $GFILLINTERIOR – Fills the figure using the current color and fill mask.
• $GBORDER – Does not fill the figure.

x1, y1
(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2
(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

x3, y3
(Input) INTEGER(2). Viewport coordinates of start vector.

x4, y4
(Input) INTEGER(2). Viewport coordinates of end vector.

wx1, wy1
(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2
(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

wx3, wy3
(Input) REAL(8). Window coordinates of start vector.

wx4, wy4
(Input) REAL(8). Window coordinates of end vector.

Results:
The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the pie is clipped or partially out of bounds, the pie is considered successfully drawn and the return is 1. If the pie is drawn completely out of bounds, the return is 0.

The border of the pie wedge is drawn in the current color set by SETCOLORRGB.

The PIE function uses the viewport-coordinate system. The center of the arc is the center of the bounding rectangle, which is specified by the viewport-coordinate points (x1, y1) and (x2, y2). The arc starts where it intersects an imaginary line extending from the center of the arc through (x3, y3). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (x4, y4).
The PIE_W function uses the window-coordinate system. The center of the arc is the center of the bounding rectangle specified by the window-coordinate points \((wx1, wy1)\) and \((wx2, wy2)\). The arc starts where it intersects an imaginary line extending from the center of the arc through \((wx3, wy3)\). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through \((wx4, wy4)\).

The fill flag option \$GFILLINTERIOR is equivalent to a subsequent call to FLOODFILLRGB using the center of the pie as the starting point and the current graphics color (set by SETCOLORRGB) as the fill color. If you want a fill color different from the boundary color, you cannot use the \$GFILLINTERIOR option. Instead, after you have drawn the pie wedge, change the current color with SETCOLORRGB and then call FLOODFILLRGB. You must supply FLOODFILLRGB with an interior point in the figure you want to fill. You can get this point for the last drawn pie or arc by calling GETARCINFO.

If you fill the pie with FLOODFILLRGB, the pie must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE. The PIE routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the Pie routine by including the IFWIN module, you need to specify the routine name as MSFWINS$Pie. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

Example
! build as Graphics App.
USE IFQWIN
INTEGER(2) status, dummy
INTEGER(2) x1, y1, x2, y2, x3, y3, x4, y4
x1 = 80; y1 = 50
x2 = 180; y2 = 150
x3 = 110; y3 = 80
x4 = 90; y4 = 180
status = SETCOLOR(INT2(4))
dummy = PIE ($GFILLINTERIOR, x1, y1, x2, y2, &
   x3, y3, x4, y4)
END

The following figure shows the coordinates used to define PIE and PIE_W:

POLYBEZIER, POLYBEZIER_W

Graphics Functions: Draw one or more Bezier curves. These functions are only available on Windows® systems.

Module: USE IFQWIN

Syntax
result = POLYBEZIER (ppoints, cpoints)
result = POLYBEZIER_W (wppoints, cpoints)

ppoints
(Input) Derived type xycoord. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
   INTEGER(2) xcoord
   INTEGER(2) ycoord
END TYPE xycoord
```

cpoints
(Input) INTEGER(2). Number of points in ppoints or wppoints.

wppoints
(Input) Derived type wxycoord. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type wxycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE wxycoord
   INTEGER(2) xcoord
   INTEGER(2) ycoord
END TYPE wxycoord
```
TYPE wxycoord
   REAL(8) wx
   REAL(8) wy
END TYPE wxycoord

Results:
The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.
A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point,
the next two points are control points, and last point is the ending point. The starting point must be
given for the first curve; subsequent curves use the ending point of the previous curve as their
starting point. So, cpoints should contain 4 for one curve, 7 for 2 curves, 10 for 3 curves, and so
forth.

POLYBEZIER does not use or change the current graphics position.

read(*,*)

END PROGRAM Bezier

**POLYBEZIERTO, POLYBEZIERTO_W**

**Graphics Functions:** Draw one or more Bezier curves. These functions are only available on Windows® systems.
Module: USE IFQWIN

Syntax

\[
\text{result} = \text{POLYBEZIERTO} (\text{ppoints}, \text{cpoints})
\]
\[
\text{result} = \text{POLYBEZIERTO}_W (\text{wppoints}, \text{cpoints})
\]

\text{ppoints}

(Input) Derived type \text{xycoord}. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type \text{xycoord} is defined in IFQWIN.F90 as follows:

\[
\begin{align*}
\text{TYPE xycoord} \\
\qquad \text{INTEGER(2) xcoord} \\
\qquad \text{INTEGER(2) ycoord}
\end{align*}
\]

\text{END TYPE xycoord}

\text{cpoints}

(Input) INTEGER(2). Number of points in \text{ppoints} or \text{wppoints}.

\text{wppoints}

(Input) Derived type \text{wxycoord}. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type \text{wxycoord} is defined in IFQWIN.F90 as follows:

\[
\begin{align*}
\text{TYPE wxycoord} \\
\qquad \text{REAL(8) wx} \\
\qquad \text{REAL(8) wy}
\end{align*}
\]

\text{END TYPE wxycoord}

Results:

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point is the current graphics position as set by MOVETO for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, \text{cpoints} should contain 3 for one curve, 6 for 2 curves, 9 for 3 curves, and so forth.

POLYBEZIERTO moves the current graphics position to the ending point of the last curve drawn.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

See the example in "POLYBEZIER, POLYBEZIER_W".
POLYGON, POLYGON_W

Graphics Functions: Draw a polygon using the current graphics color, logical write mode, and line style. These functions are only available on Windows® systems.

Module: USE IFQWIN

Syntax

result = POLYGON (control, ppoints, cpoints)
result = POLYGON_W (control, wppoints, cpoints)

control
(Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in IFQWIN.F90):

• $GFILLINTERIOR – Draws a solid polygon using the current color and fill mask.
• $GBORDER – Draws the border of a polygon using the current color and line style.

ppoints
(Input) Derived type xycoord. Array of derived types defining the polygon vertices in viewport coordinates. The derived type xycoord is defined in IFQWIN.F90 as follows:

TYPE xycoord
    INTEGER(2) xcoord
    INTEGER(2) ycoord
END TYPE xycoord

cpoints
(Input) INTEGER(2). Number of polygon vertices.

wppoints
(Input) Derived type wxycoord. Array of derived types defining the polygon vertices in window coordinates. The derived type wxycoord is defined in IFQWIN.F90 as follows:

TYPE wxycoord
    REAL(8) wx
    REAL(8) wy
END TYPE wxycoord

Results:
The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.
The border of the polygon is drawn in the current graphics color, logical write mode, and line style, set with SETCOLORRGB, SETWRITEMODE, and SETLINESTYLE, respectively. The POLYGON routine uses the viewport-coordinate system (expressed in xycoord derived types), and the POLYGON_W routine uses real-valued window coordinates (expressed in wxycoord types).

The arguments ppoints and wppoints are arrays whose elements are xycoord or wxycoord derived types. Each element specifies one of the polygon’s vertices. The argument cpoints is the number of elements (the number of vertices) in the ppoints or wppoints array.

Note that POLYGON draws between the vertices in their order in the array. Therefore, when drawing outlines, skeletal figures, or any other figure that is not filled, you need to be careful about the order of the vertices. If you don’t want lines between some vertices, you may need to repeat vertices to make the drawing backtrack and go to another vertex to avoid drawing across your figure. Also, POLYGON draws a line from the last specified vertex back to the first vertex.

If you fill the polygon using FLOODFILLRGB, the polygon must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE. The POLYGON routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Polygon routine by including the IFWIN module, you need to specify the routine name as MSFWINS$Polygon. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

Compatibility

Example
! Build as a Graphics App.
!
! Draw a skeletal box
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) poly(12)
! Set up box vertices in order they will be drawn, &
! repeating some to avoid unwanted lines across box
poly(1)%xcoord = 50
poly(1)%ycoord = 80
poly(2)%xcoord = 85
poly(2)%ycoord = 35
poly(3)%xcoord = 185
poly(3)%ycoord = 35
poly(4)%xcoord = 150
poly(4)%ycoord = 80
poly(5)%xcoord = 50
poly(5)%ycoord = 80
poly(6)%xcoord = 50
poly(6)%ycoord = 180
poly(7)%xcoord = 150
poly(7)%ycoord = 180
poly(8)%xcoord = 185
poly(8)%ycoord = 135
poly(9)%xcoord = 185
poly(9)%ycoord = 35
poly(10)%xcoord = 150
poly(10)%ycoord = 80
poly(11)%xcoord = 150
poly(11)%ycoord = 180
poly(12)%xcoord = 150
poly(12)%ycoord = 80
status = SETCOLORRGB(Z’0000FF’)
status = POLYGON($GBORDER, poly, INT2(12))
END

POLYLINEQQ

**Graphics Function:** Draws a line between each successive x, y point in a given array. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```
result = POLYLINEQQ (points, cnt)
```
points

(Input) An array of DF_POINT objects. The derived type DF_POINT is defined in IFQWIN.F90 as:

```fortran
  type DF_POINT
    sequence
    integer(4) x
    integer(4) y
  end type DF_POINT
```

cnt

(Input) INTEGER(4). Number of elements in the points array.

Results:
The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, zero.
POLYLINEQQ uses the viewport-coordinate system.
The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.
The current graphics position is not used or changed as it is in the LINETO function.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS

See Also: "LINETO, LINETO_W", "LINETOAREX", "SETCOLORRGB", "SETLINESTYLE", "SETWRITEMODE"

Example

```fortran
! Build for QuickWin or Standard Graphics
USE IFQWIN
TYPE(DF_POINT) points(12)
integer(4) result
integer(4) cnt, i
! load the points
do i = 1,12,2
    points(i).x =20*i
    points(i).y =10
    points(i+1).x =20*i
    points(i+1).y =60
end do
! A sawtooth pattern will appear in the upper left corner
```
result = POLYLINEQQ(points, 12)
end

PUTC

**Portability Function:** Writes a character to Fortran external unit 6.

**Module:** USE IFPORT

**Syntax**

result = PUTC (char)

**char**

(Input) Character. Character to be written to external unit 6.

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “GETC”, “FPUTC”, WRITE and PRINT in the Language Reference

**Example**

use IFPORT
integer(4) i4
character*1 char1
do i = 1,26
   char1 = char(123-i)
   i4 = putc(char1)
   if (i4.ne.0) iflag = 1
enddo

PUTIMAGE, PUTIMAGE_W

**Graphics Subroutines:** Transfer the image stored in memory to the screen. These subroutines are only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

CALL PUTIMAGE (x, y, image, action)
CALL PUTIMAGE_W (wx, wy, image, action)
x, y
(Input) INTEGER(2). Viewport coordinates for upper-left corner of the image when placed on the screen.

wx, wy
(Input) REAL(8). Window coordinates for upper-left corner of the image when placed on the screen.

image

action
(Input) INTEGER(2). Interaction of the stored image with the existing screen image. One of the following symbolic constants (defined in IFQWIN.F90):

- $GAND – Forms a new screen display as the logical AND of the stored image and the existing screen display. Points that have the same color in both the existing screen image and the stored image remain the same color, while points that have different colors are joined by a logical AND.
- $GOR – Superimposes the stored image onto the existing screen display. The resulting image is the logical OR of the image.
- $GPRESET – Transfers the data point-by-point onto the screen. Each point has the inverse of the color attribute it had when it was taken from the screen by GETIMAGE, producing a negative image.
- $GPSET – Transfers the data point-by-point onto the screen. Each point has the exact color attribute it had when it was taken from the screen by GETIMAGE.
- $GXOR – Causes points in the existing screen image to be inverted wherever a point exists in the stored image. This behavior is like that of a cursor. If you perform an exclusive OR of an image with the background twice, the background is restored unchanged. This allows you to move an object around without erasing the background. The $GXOR constant is a special mode often used for animation.

In addition, the following ternary raster operation constants can be used (described in the online documentation for the Windows® API BitBlt):

- $GSRCCOPY (same as $GPSET)
- $GSRCPAINT (same as $GOR)
- $GSRCAND (same as $GAND)
- $GSRCINVERT (same as $GXOR)
- $GSRCERASE
- $GNOTSRCCOPY (same as $GPRESET)
- $GNOTSRCERASE
PUTIMAGE places the upper-left corner of the image at the viewport coordinates (x, y).
PUTIMAGE_W places the upper-left corner of the image at the window coordinates (wx, wy).

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETIMAGE, GETIMAGE_W”, “GRSTATUS”, “IMAGESIZE, IMAGESIZE_W”

Example
! Build as a Graphics App.
USE IFQWIN
INTEGER(1), ALLOCATABLE :: buffer(:)
INTEGER(2) status, x
INTEGER(4) imsize

status = SETCOLOR(INT2(4))
! draw a circle
status = ELLIPSE($GFILLINTERIOR,INT2(40),INT2(55), &
               INT2(70),INT2(85))
imsize = IMAGESIZE (INT2(39),INT2(54),INT2(71), &
                    INT2(86))
ALLOCATE (buffer(imsize))
CALL GETIMAGE (INT2(39),INT2(54),INT2(71),INT2(86), &
               buffer)
! copy a row of circles beneath it
DO x = 5 , 395, 35
   CALL PUTIMAGE(x, INT2(90), buffer, $GPSET)
END DO
DEALLOCATE(buffer)
END
**PXF<TYPE>GET**

**POSIX Subroutine:** Gets the value stored in a component (or field) of a structure.

**Module:** USE IFPOSIX

**Syntax**

CALL PXF<TYPE>GET (jhandle, compname, value, ierror)

CALL PXF<TYPE>GET (jhandle, compname, value, ilen, ierror) !when <TYPE> is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTEGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLOGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFSTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDGBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFINTE8GET</td>
</tr>
</tbody>
</table>

**jhandle**

(Input) INTEGER(4). A handle of a structure.

**compname**

(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value**

(Output) A variable, whose data type depends on the value of <TYPE>. See the table above for the data types for each value; for example, if the value for <TYPE> is INT, the data type is INTEGER(4). Stores the value of the component (or field).

**ilen**

(Output) INTEGER(4). This argument can only be used when <TYPE> is STR (PXFSTRGET). Stores the length of the returned string.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXF<TYPE>GET subroutines retrieve the value from component (or field) compname of the structure associated with handle jhandle into variable value.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: "PXF<TYPE>SET"

Example

See the example in "PXFTIMES" (which demonstrates PXFINTGET and PXFINT8GET)

**PXF<TYPE>SET**

**POSIX Subroutine:** Sets the value of a component (or field) of a structure.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXF<TYPE>SET (jhandle, compname, value, ierror)
CALL PXF<TYPE>SET (jhandle, compname, value, ilen, ierror) !when <TYPE> is STR
```

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTSET</td>

### PXFA<TYPE>GET

**POSIX Subroutine:** Sets the value of an array component (or field) of a structure.

**Module:** USE IFPOSIX

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8GET</td>
</tr>
</tbody>
</table>

**jhandle**
(Input) INTEGER(4). A handle of a structure.

**compname**
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value**
(Output) An array, whose data type depends on the value of <TYPE>. See the table above for the data types for each value; for example, if the value for <TYPE> is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).

**ialen**
(Input) INTEGER(4). The size of array value.

**ilen**
(Output) INTEGER(4). This argument can only be used when <TYPE> is STR (PXFASTRGET). An array that stores the lengths of elements of array value.

**ierror**
(Output) INTEGER(4). The error status. If successful, ierror is set to zero; otherwise, an error code.

The PXFA<TYPE>GET subroutines are similar to the PXF<TYPE>GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA<TYPE>GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**Compatibility**

<table>
<thead>
<tr>

<th>GRAPHICS</th>
<th>QUICKWIN</th>
<th>GRAPHICS</th>
<th>WINDOWS</th>
<th>DLL</th>
<th>LIB</th>
</tr>
</thead>
</table>

See Also: “PXFA<TYPE>SET”, “PXF<TYPE>GET”

---

2-264
Syntax

CALL PXFA<TYPE>SET (jhandle, compname, value, ialen, ierror)
CALL PXFA<TYPE>SET (jhandle, compname, value, ialen, ilen, ierror)  ! when <TYPE> is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXAFINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFAREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFALGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFASTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFACHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8SET</td>
</tr>
</tbody>
</table>

**jhandle**
(Input) INTEGER(4). A handle of a structure.

**compname**
(Input) Character. The name of the component (or field) of the structure to write data to.

**value**
(Input) An array, whose data type depends on the value of <TYPE>. See the table above for the data types for each value; for example, if the value for <TYPE> is INT, the data type of the array is INTEGER(4). The value for the component (or field).

**ialen**
(Input) INTEGER(4). The size of array value.

**ilen**
(Input) INTEGER(4). This argument can only be used when <TYPE> is STR (PXFASTRSET). An array that specifies the lengths of elements of array value.

**ierror**
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA<TYPE>SET subroutines are similar to the PXF<TYPE>SET subroutines, but they should be used when the component (or field) of the structure is an array.
When the PXFA<TYPE>SET subroutines are used, the entire array is accessed (written to the component or field) as a unit.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: “PXFA<TYPE>GET”, "PXF<TYPE>SET"

**PXFACCESS**

**POSIX Subroutine:** Determines the accessibility of a file.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFACCESS (path, ilen, iamode, ierror)

**path**

(Input) Character. The name of the file.

**ilen**

(Input) INTEGER(4). The length of the path string.

**iamode**

(Input) INTEGER(4). One or more of the following:

<table>
<thead>
<tr>
<th>Code</th>
<th>Access Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Checks for existence of the file.</td>
</tr>
<tr>
<td>1</td>
<td>Checks for execute permission.</td>
</tr>
<tr>
<td>2</td>
<td>Checks for write access.</td>
</tr>
<tr>
<td>4</td>
<td>Checks for read access.</td>
</tr>
<tr>
<td>6</td>
<td>Checks for read/write access.</td>
</tr>
</tbody>
</table>

1. L’X only

**ierror**

(Output) INTEGER(4). The error status.

If access is permitted, the result value is zero; otherwise, an error code. Possible error codes are:

- –1: A bad parameter was passed.
- ENOENT: The named directory does not exist.
- EACCES: Access requested was denied.

On Windows* systems, if the name given is a directory name, the function only checks for existence. All directories have read/write access on Windows systems.
PXFALARM

POSIX Subroutine: Schedules an alarm.
Module: USE IFPOSIX
Syntax

    CALL PXFALARM (iseconds, isecleft, ierror)

iseconds
(Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.

isecleft
(Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered. It is set to zero if there was no previously scheduled alarm signal.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The PXFALARM subroutine arranges for a SIGALRM signal to be delivered to the process in seconds isecends.

On Linux* and Mac OS* systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

Compatibility
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: “PXFCONST”, “IPXFCONST”, “PXFSIGACTION”

PXFCALLSUBHANDLE

POSIX Subroutine: Calls the associated subroutine.
Module: USE IFPOSIX
CALL PXFCALLSUBHANDLE (jhandle2, ival, ierror)

jhandle2
(Input) INTEGER(4). A handle to the subroutine.

ival
(Input) INTEGER(4). The argument to the subroutine.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine.
PXFGETSUBHANDLE should be used to obtain a subroutine handle.

NOTE. The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

Compatibility
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: “PXFGETSUBHANDLE”

PXFCFGETISPEED

POSIX Subroutine: Returns the input baud rate from a termios structure. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax
CALL PXFCFGETISPEED (jtermios, iospeed, ierror)

jtermios
(Input) INTEGER(4). A handle of structure termios.

iospeed
(Output) INTEGER(4). The returned value of the input baud rate from the structure associated with handle jtermios.
**ierror**
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

**NOTE.** To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFCFSETOSPEED”

### PXFCFGETOSPEED

**POSIX Subroutine:** Returns the output baud rate from a termios structure. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFCFGETOSPEED (jtermios, iospeed, ierror)

**jtermios**
(Input) INTEGER(4). A handle of structure termios.

**iospeed**
(Output) INTEGER(4). The returned value of the output baud rate from the structure associated with handle *jtermios*.

**ierror**
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

**NOTE.** To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFCFSETOSPEED”
PXFCFSETISPEED

**POSIX Subroutine:** Sets the input baud rate in a termios structure. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFCFSETISPEED (jtermios, ispeed, ierror)
```

- **jtermios**
  - (Input) INTEGER(4). A handle of structure termios.

- **ispeed**
  - (Input) INTEGER(4). The value of the input baud rate for the structure associated with handle jtermios.

- **ierror**
  - (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

---

**NOTE.** To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

**See Also:** “PXFSTRUCTCREATE”, “PXFCFGETISPEED”

---

PXFCFSETOSPEED

**POSIX Subroutine:** Sets the output baud rate in a termios structure. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFCFSETOSPEED (jtermios, ispeed, ierror)
```

- **jtermios**
  - (Input) INTEGER(4). A handle of structure termios.

- **ispeed**
  - (Input) INTEGER(4). The value of the output baud rate for the structure associated with handle jtermios.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

NOTE. To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFCFGETOSPEED”

PXFCHDIR

POSIX Subroutine: Changes the current working directory.
Module: USE IFPOSIX
Syntax
    CALL PXFCHDIR (path, ilen, ierror)

path
(Input) Character. The directory to be changed to.
ilen
(Input) INTEGER(4). The length of the path string.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PXFMKDIR”

PXFCHMOD

POSIX Subroutine: Changes the ownership mode of the file.
Module: USE IFPOSIX
Syntax
    CALL PXFCHMOD (path, ilen, imode, ierror)
path
(Input) Character. The path to the file.

ilen
(Input) INTEGER(4). The length of the path string.

imode
(Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++* Installation in the /include directory under sys/stat.h for the values of imode. On Linux* and Mac OS* systems, use octal file-access mode.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

NOTE. On Linux and Mac OS systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFCCHOWN

POSIX Subroutine: Changes the owner and group of a file. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax
CALL PXFCCHOWN (path, ilen, iowner, igroup, ierror)

path
(Input) Character. The file or directory name.

ilen
(Input) INTEGER(4). The length of the path string.

iowner
(Input) INTEGER(4). The owner UID.
**igroup**
(Input) INTEGER(4). The group GID.

**ierror**
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

---

**PXFCLEARENV**

**POSIX Subroutine:** Clears the process environment.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFCLEARENV (ierror)
```

**ierror**
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.
After a call to PXFCLEARENV, no environment variables are defined.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

---

**PXFCLOSE**

**POSIX Subroutine:** Closes the file associated with the descriptor.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFCLOSE (fd, ierror)
```

**fd**
(Input) INTEGER(4). A file descriptor.

**ierror**
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “PXFOPEN”
**PXFCLOSEDIR**

**POSIX Subroutine:** Closes the directory stream.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFCLOSEDIR (idirid, ierror)
```

- **idirid** (Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with *idirid*.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: “PXFOPENDIR”

---

**PXFCNTL**

**POSIX Subroutine:** Manipulates an open file descriptor. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFCNTL (ifildes, icmd, iargin, iargout, ierror)
```

- **ifildes** (Input) INTEGER(4). A file descriptor.
- **icmd** (Input) INTEGER(4). Defines an action for the file descriptor.
- **iargin** (Input; output) INTEGER(4). Interpretation of this argument depends on the value of *icmd*.
- **iargout** (Output) INTEGER(4). Interpretation of this argument depends on the value of *icmd*.
- **ierror** (Output) INTEGER(4). The error status.
If successful, `ierror` is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in `icmd`, can be obtained by using the values of predefined macros in C header `fcntl.h`, or by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>F_DUPFD</code></td>
<td>Returns into <code>iargout</code> the lowest available unopened file descriptor greater than or equal to <code>iargin</code>. The new file descriptor refers to the same open file as <code>ifildes</code> and shares any locks. The system flag <code>FD_CLOEXEC</code> for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.</td>
</tr>
<tr>
<td><code>F_GETFD</code></td>
<td>Returns into <code>iargout</code> the value of system flag <code>FD_CLOEXEC</code> associated with <code>ifildes</code>. In this case, <code>iargin</code> is ignored.</td>
</tr>
<tr>
<td><code>F_SETFD</code></td>
<td>Sets or clears the system flag <code>FD_CLOEXEC</code> for file descriptor <code>ifildes</code>. The PXFEXEC family of functions will close all file descriptors with the <code>FD_CLOEXEC</code> flag set. The value for <code>FD_CLOEXEC</code> is obtained from argument <code>iargin</code>.</td>
</tr>
</tbody>
</table>
| `F_GETFL` | Returns the file status flags for file descriptor `ifildes`. Unlike `F_GETFD`, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for PXFCONST or IPXFCONST, can be returned:
  - `O_APPEND` – Specifies the file is opened in append mode.
  - `O_NONBLOCK` – Specifies when the file is opened, it does not block waiting for data to become available.
  - `O_RDONLY` – Specifies the file is opened for reading only.
  - `O_RDWR` – Specifies the file is opened for both reading and writing.
  - `O_WRONLY` – Specifies the file is opened for writing only. |
| `F_SETFL` | Sets the file status flags from `iargin` for file descriptor `ifildes`. Only `O_APPEND` or `O_NONBLOCK` flags can be modified. In this case, `iargout` is ignored. |
| `F_GETLK` | Gets information about a lock. Argument `iargin` must be a handle of structure `flock`. This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle `iargin`. If there are no locks in place that would prevent the lock from being locked, field `l_type` in the structure is set to the value of the constant with symbolic name `F_UNLCK`. |
| `F_SETLK` | Sets or clears a lock. Argument `iargin` must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field `l_type`. If the lock is busy, an error is returned. |
| `F_SETLKW` | Sets or clears a lock, but causes the process to wait if the lock is busy. Argument `iargin` must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field `l_type`. If the lock is busy, PXFCNTL waits for an unlock. |
NOTE. To get a handle for an instance of the flock structure, use PXFSTRUCTCREATE with the string 'flock' for the structure name.

See Also: "PXFSTRUCTCREATE", "IPXFCONST", "PXFCNST"

PXFCNST

**POSIX Subroutine:** Returns the value associated with a constant.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFCNST (constname, ival, ierror)
```

*constname*

(Input) Character. The name of one of the following constants:

- STDIN_UNIT
- STDOUT_UNIT
- STDERR_UNIT
- EINVAL
- ENONAME
- ENOHANDLE
- EARRAYLEN

The constants beginning with E signify various error values for the system variable `errno`.

*ival*

(Output) INTEGER(4). The returned value of the constant.

*ierror*

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

For more information on these constants, see your Microsoft Visual C++ documentation (Windows* systems) or the errno.h file (Linux* and Mac OS* systems).

**Compatibility**

**CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB**

See Also: "PXFISCONST"
PXFCREAT

**POSIX Subroutine**: Creates a new file or rewrites an existing file.

**Module**: USE IFPOSIX

**Syntax**

```call pxfcreat (path, ilen, imode, ifildes, ierror)
```

- **path**
  - (Input) Character. The pathname of the file.
- **ilen**
  - (Input) INTEGER(4). The length of path string.
- **imode**
  - (Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* and Mac OS* systems, use octal file-access mode.
- **ifildes**
  - (Output) INTEGER(4). The file descriptor.
- **ierror**
  - (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

PXFCTERMID

**POSIX Subroutine**: Generates a terminal pathname. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module**: USE IFPOSIX

**Syntax**

```call pxfctermid (s, ilen, ierror)
```

- **s**
  - (Output) Character. The returned pathname of the terminal.
- **ilen**
  - (Output) INTEGER(4). The length of the returned value in the s string.
**ierror**

(Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

This subroutine returns a string that refers to the current controlling terminal for the current process.

---

**PXFDUP, PXFDUP2**

**POSIX Subroutine:** Duplicates an existing file descriptor.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFDUP (ifildes, ifid, ierror)

CALL PXFDUP2 (ifildes, ifildes2, ierror)

**ifildes**

(Input) INTEGER(4). The file descriptor to duplicate.

**ifid**

(Output) INTEGER(4). The returned new duplicated file descriptor.

**ifildes2**

(Output) INTEGER(4). The number for the new file descriptor.

**ierror**

(Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFDUP subroutine creates a second file descriptor for an opened file.

The PXFDUP2 subroutine copies the file descriptor associated with **ifildes**. Integer number **ifildes2** becomes associated with this new file descriptor, but the value of **ifildes2** is not changed.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

---

**PXFE<TYPE>GET**

**POSIX Subroutine:** Gets the value stored in an array element component (or field) of a structure.

**Module:** USE IFPOSIX
Syntax

CALL PXFE<TYPE>GET (jhandle, compname, index, value, ierror)

CALL PXFE<TYPE>GET (jhandle, compname, index, value, ilen, ierror)  ! when <TYPE> is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXEFINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8GET</td>
</tr>
</tbody>
</table>

jhandle
(Input) INTEGER(4). A handle of a structure.

compname
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

index
(Input) INTEGER(4). The index of the array element to get data for.

value
(Output) A variable, whose data type depends on the value of <TYPE>. See the table above for the data types for each value; for example, if the value for <TYPE> is INT, the data type is INTEGER(4). Stores the value of the component (or field).

ilen
(Output) INTEGER(4). This argument can only be used when <TYPE> is STR (PXFESTRGET). Stores the length of the returned string.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFE<TYPE>GET subroutines are similar to the PXF<TYPE>GET subroutines, but they should be used when the component (or field) of the structure is an array.
When the PXFE<TYPE>GET subroutines are used, the array element with index index is accessed (read from the component or field).

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: "PXFE<TYPE>SET", "PXF<TYPE>GET"

**PXFE<TYPE>SET**

**POSIX Subroutine:** Sets the value of an array element component (or field) of a structure.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFE<TYPE>SET (jhandle, compname, index, value, ierror)

CALL PXFE<TYPE>SET (jhandle, compname, index, value, ilen, ierror) ! when <TYPE> is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXEFINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFEREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*()</td>
<td>PXFESTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8SET</td>
</tr>
</tbody>
</table>

**jhandle**

(Input) INTEGER(4). A handle of a structure.

**compname**

(Input) Character. The name of the component (or field) of the structure to write data to.

**index**

(Input) INTEGER(4). The index of the array element to write data to.
Descriptions of the Library Routines

value
(Input) A variable, whose data type depends on the value of <TYPE>. See the table above for the data types for each value; for example, if the value for <TYPE> is INT, the data type is INTEGER(4). The value for the component (or field).

ilen
(Input) INTEGER(4). This argument can only be used when <TYPE> is STR (PXFESTRSET). The length of the string value.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFE<TYPE>SET subroutines are similar to the PXF<TYPE>SET subroutines, but they should be used when the component (or field) of the structure is an array.
When the PXFE<TYPE>SET subroutines are used, the array element with index index is accessed (written to the component or field).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: "PXFE<TYPE>GET", "PXF<TYPE>SET"

PXFEEXECV

POSIX Subroutine: Executes a new process by passing command-line arguments.
Module: USE IFPOSIX
Syntax
CALL PXFEEXECV (path, lenpath, argv, lenargv, iargc, ierror)
path
(Input) Character. The path to the new executable process.
lenpath
(Input) INTEGER(4). The length of path string.
argv
(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
lenargv
(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

iargc
(Input) INTEGER(4). The number of command-line arguments.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. If execution is successful, no return is made to the calling process.

Compatibility
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: “PXFEXECVE”, “PXFEXECVP”

PXFEXECVE

POSIX Subroutine: Executes a new process by passing command-line arguments.
Module: USE IFPOSIX
Syntax
CALL PXFEXECVE (path, lenpath, argv, lenargv, iargc, env, lenenv, ienvc, ierror)

path
(Input) Character. The path to the new executable process.

lenpath
(Input) INTEGER(4). The length of path string.

argv
(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

lenargv
(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

iargc
(Input) INTEGER(4). The number of command-line arguments.
Descriptions of the Library Routines

env
(Input) An array of character strings. Contains the environment settings for the new process.

lenenv
(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in env.

ienvc
(Input) INTEGER(4). The number of environment settings in env.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array and environment settings specified in the env array.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PXFEXECV”, “PXFEXECVP”

PXFEXECVP

POSIX Subroutine: Executes a new process by passing command-line arguments.
Module: USE IFPOSIX
Syntax

CALL PXFEXECVP (file, lenfile, argv, lenargv, iargc, ierror)

file
(Input) Character. The filename of the new executable process.

lenfile
(Input) INTEGER(4). The length of file string.

argv
(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

lenargv
(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.
pxfexecvp subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. It uses the PATH environment variable to find the file to execute.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "PXFEXECV", "PXFEXECVE"

PXEXIT, PXFFASTEXIT
POSIX Subroutine: Exits from a process.
Module: USE IFPOSIX

Syntax
CALL PXEXIT (istatus)
CALL PXFFASTEXIT (istatus)

istatus
(Input) INTEGER(4). The exit value.

The PXEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions atexit and onexit, and flushes all file buffers before terminating the process. The istatus value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing atexit or onexit, and without flushing stream buffers.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
    print *," I am a child process"
    print *," My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET, IERROR)
    print *," The pid of my parent is",IPID_RET
    print *," Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
else
    print *," I am a parent process"
    print *," My parent pid is ", IPID_RET
    print *," I am creating the process with pid", IPID
    print *," Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The child with pid ", IPID_RET," has exited"
    if( PXFWIFEXITED(ISTAT) ) then
        print *, " The child exited normally"
        istat_ret = IPXFWEXITSTATUS(ISTAT)
        print 10," The low byte of the child exit code is", istat_ret
    end if
end if
10 FORMAT (A,Z)
end program

PXFFDOPEN

**POSIX Subroutine**: Opens an external unit.

**Module**: USE IFPOSIX

**Syntax**

```
CALL PXFFDOPEN (ifildes, iunit, access, ierror)
```

*ifildes*

(Input) INTEGER(4). The file descriptor of the opened file.

*iunit*

(Input) INTEGER(4). The Fortran logical unit to connect to file descriptor *ifildes*. 
access

(Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Possible Values</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NEWLINE'</td>
<td>'YES' or 'NO'</td>
<td>I/O type</td>
<td>'YES'</td>
</tr>
<tr>
<td>'BLANK'</td>
<td>'NULL' or 'ZERO'</td>
<td>Interpretation of blanks</td>
<td>'NULL'</td>
</tr>
<tr>
<td>'STATUS'</td>
<td>'OLD', 'SCRATCH', or 'UNKNOWN'</td>
<td>File status at open</td>
<td>'UNKNOWN'</td>
</tr>
<tr>
<td>'FORM'</td>
<td>'FORMATTED' or 'UNFORMATTED'</td>
<td>Format type</td>
<td>'FORMATTED'</td>
</tr>
</tbody>
</table>

Keywords should be separated from their values by the equals ('=') character; for example:

```fortran
CALL PXFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN', IERROR)
```

**ierror**

(Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by `iunit` to a file descriptor `ifildes`. If the unit is already connected to a file, the file should be closed before using PXFFDOPEN.

**NOTE.** On Windows* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error. To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

**Compatibility**

| CONSOLE  | STANDARD GRAPHICS | QUICKWIN GRAPHICS | WINDOWS | DLL | LIB |

**PXFFFlush**

**POSIX Subroutine**: Flushes a file directly to disk.

**Module**: USE IFPOSIX

**Syntax**

```fortran
CALL PXFFFLUSH (lunit, ierror)
```
lunit
(Input) INTEGER(4). A Fortran logical unit.

derror
(Output) INTEGER(4). The error status.
If successful, \texttt{derror} is set to zero; otherwise, an error code.
The PXFFFlush subroutine writes any buffered output to the file connected to unit \textit{lunit}.

\textbf{Compatibility}
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\textbf{PXFFGETC}

\textbf{POSIX Subroutine}: Reads a character from a file.
\textbf{Module}: USE IFPOSIX
\textbf{Syntax}
\begin{verbatim}
call pxffgetc (lunit, char, derror)
\end{verbatim}
\textit{lunit}
(Input) INTEGER(4). A Fortran logical unit.
\textit{char}
(Input) Character. The character to be read.
\textit{derror}
(Output) INTEGER(4). The error status.
If successful, \texttt{derror} is set to zero; otherwise, an error code.
The PXFFGETC subroutine reads a character from a file connected to unit \textit{lunit}.

\textbf{Compatibility}
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\textbf{See Also:} “\textit{PXFFPUTC}”

\textbf{PXFFILENO}

\textbf{POSIX Subroutine}: Returns the file descriptor associated with a specified unit.
\textbf{Module}: USE IFPOSIX
\textbf{Syntax}
\begin{verbatim}
call pxffilen (lunit, fd, derror)
\end{verbatim}

\texttt{PXFFPUTC}
lunit
(Input) INTEGER(4). A Fortran logical unit.

fd
(Output) INTEGER(4). The returned file descriptor.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. Possible error codes are:

• EINV AL: lunit is not an open unit.
• EBADF: lunit is not connected with a file descriptor.

The PXFFILENO subroutine returns in fd the file descriptor associated with lunit.

NOTE. On Windows* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

Compatibility
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

PXFFORK

POSIX Subroutine: Creates a child process that differs from the parent process only in its PID. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

CALL PXFFORK (ipid, ierror)

ipid
(Output) INTEGER(4). The returned PID of the new child process.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent's thread of execution, and a zero is returned in the child's thread of execution. Otherwise, −1 is returned in the parent's context and no child process is created.

**See Also:** “IPXFWEXITSTATUS”

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
call PXFGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid", IPID
   print *," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program
```
PXFFPATHCONF

**POSIX Subroutine:** Gets the value for a configuration option of an opened file.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFFPATHCONF (ifildes, name, ival, ierror)
```

- **ifildes**  
  (Input) INTEGER(4). The file descriptor of the opened file.

- **name**  
  (Input) INTEGER(4). The configurable option.

- **ival**  
  (Output) INTEGER(4). The value of the configurable option.

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor **ifildes**.

The configuration option, defined in **name**, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If <strong>ifildes</strong> refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON^1</td>
<td>Returns the maximum length of a formatted input line; the file descriptor <strong>ifildes</strong> must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT^1</td>
<td>Returns the maximum length of an input line; the file descriptor <strong>ifildes</strong> must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in <strong>ifildes</strong> that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when <strong>ifildes</strong> is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the file descriptor <strong>ifildes</strong> must refer to a pipe or FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED^1</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If <strong>ifildes</strong> refers to a directory, then this applies to all files in that directory.</td>
</tr>
</tbody>
</table>
On Linux* and Mac OS* systems, the corresponding macros are defined in `<unistd.h>`. The values for `name` can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in `<unistd.h>`. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>_POSIX_PATH_MAX</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>_POSIX_CHOWN_RESTRICTED</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NO_TRUNC</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
</tbody>
</table>

1. L*X, M*X32

See Also: "IPXFCONST", "PXFCONST", "PXFPATHCONF"

**PXFFPUTC**

**POSIX Subroutine:** Writes a character to a file.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFFPUTC (lunit, char, ierror)
```

- **lunit**
  - (Input) INTEGER(4). A Fortran logical unit.
- **char**
  - (Input) Character. The character to be written.
ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit lunit.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "PXFFGETC"

PXFFSEEK

POSIX Subroutine: Modifies a file position.

Module: USE IFPOSIX

Syntax
CALL PXFFSEEK (lunit, ioffset, iwhence, ierror)

lunit
(Input) INTEGER(4). A Fortran logical unit.

ioffset
(Input) INTEGER(4). The number of bytes away from iwhence to place the pointer.

iwhence
(Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in stdio.h):

• SEEK_SET = 0
  Offset from the beginning of the file.

• SEEK_CUR = 1
  Offset from the current position of the file pointer.

• SEEK_END = 2
  Offset from the end of the file.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. Possible error codes are:

• EINVAL: No file is connected to lunit, iwhence is not a proper value, or the resulting offset is invalid.
• ESPipe: \( lunit \) is a pipe or FIFO.
• EEND: The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit \( lunit \).

**Compatibility**
console standard graphics quickwin graphics windows dll lib

**PXFFSTAT**

**POSIX Subroutine:** Gets a file's status information.

**Module:** USE IFPOSIX

**Syntax**

\[
\text{CALL PXFFSTAT} \left( \text{ifildes}, \text{jstat}, \text{ierror} \right)
\]

- **ifildes**
  (Input) INTEGER(4). The file descriptor for an opened file.
- **jstat**
  (Input) INTEGER(4). A handle of structure `stat`.
- **ierror**
  (Output) INTEGER(4). The error status.

If successful, \( ierror \) is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with \( \text{ifildes} \) into the structure associated with handle \( \text{jstat} \).

**NOTE.** To get a handle for an instance of the \`stat\` structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

**Compatibility**

console standard graphics quickwin graphics windows dll lib

**See Also:** "PXFSTRUCTCREATE"

**PXFFTELL**

**POSIX Subroutine:** Returns the relative position in bytes from the beginning of the file.

**Module:** USE IFPOSIX
Syntax

CALL PXFTELL (lunit, ioffset, ierror)

lunit
(Input) INTEGER(4). A Fortran logical unit.

ioffset
(Output) INTEGER(4). The returned relative position in bytes from the beginning of the file.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

PXGETARG

POSIX Subroutine: Gets the specified command-line argument.

Module: USE IFPOSIX

Syntax

CALL PXGETARG (argnum, str, istr, ierror)

argnum
(Input) INTEGER(4). The number of the command-line argument.

str
(Output) Character. The returned string value.

istr
(Output) INTEGER(4). The length of the returned string; it is zero if an error occurs.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXGETARG subroutine places the command-line argument with number argnum into character string str. If argnum is equal to zero, the value of the argument returned is the command name of the executable file.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
See Also: “IPXFARGC”

**PXGETATTTY**

**POSIX Subroutine**: Tests whether a file descriptor is connected to a terminal.

**Module**: USE IFPOSIX

**Syntax**

CALL PXGETATTTY (ifildes, isatty, ierror)

*ifildes*  
(Input) INTEGER(4). The file descriptor.

*isatty*  
(Output) LOGICAL(4). The returned value.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

If file descriptor *ifildes* is open and connected to a terminal, *isatty* returns .TRUE.; otherwise, .FALSE..

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**PXGETC**

**POSIX Subroutine**: Reads a character from standard input unit 5.

**Module**: USE IFPOSIX

**Syntax**

CALL PXGETC (nextcar, ierror)

*nextcar*  
(Output) Character. The returned character that was read.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
See Also: “PXFPUTC”

**PXGETCWD**

**POSIX Subroutine:** Returns the path of the current working directory.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXGETCWD (buf, ilen, ierror)
```

- **buf**
  (Output) Character. The returned pathname of the current working directory.
- **ilen**
  (Output) INTEGER(4). The length of the returned pathname.
- **ierror**
  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of buf is insufficient.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXGETEGID**

**POSIX Subroutine:** Gets the effective group ID of the current process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXGETEGID (iegid, ierror)
```

- **iegid**
  (Output) INTEGER(4). The returned effective group ID.
- **ierror**
  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. The effective ID corresponds to the set ID bit on the file being executed.
PXGETENV

**POSIX Subroutine:** Gets the setting of an environment variable.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFGETENV (name, lenname, value, lenvalue, ierror)
```

- **name**
  (Input) Character. The name of the environment variable.
- **lenname**
  (Input) INTEGER(4). The length of `name`.
- **value**
  (Output) Character. The returned value of the environment variable.
- **lenvalue**
  (Output) INTEGER(4). The returned length of `value`. If an error occurs, it returns zero.
- **ierror**
  (Output) INTEGER(4). The error status.
  If successful, `ierror` is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**See Also:** “PXFSETENV”

PXGETEUID

**POSIX Subroutine:** Gets the effective user ID of the current process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFGETEUID (ieuid, ierror)
```

- **ieuid**
  (Output) INTEGER(4). The returned effective user ID.
- **ierror**
  (Output) INTEGER(4). The error status.
  If successful, `ierror` is set to zero; otherwise, an error code.
The effective ID corresponds to the set ID bit on the file being executed.

**PXFGGETGID**

**POSIX Subroutine:** Gets the real group ID of the current process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFGGETGID (igid, ierror)
```

- `igid` (Output) INTEGER(4). The returned real group ID.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

**See Also:** “**PXFSCHOOL**”

**Example**

See the example in “**PXFGGETGROUPS**”.

**PXFGGETGRGID**

**POSIX Subroutine:** Gets group information for the specified GID. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFGGETGRGID (jgid, jgroup, ierror)
```

- `jgid` (Input) INTEGER(4). The group ID to retrieve information about.
- `jgroup` (Input) INTEGER(4). A handle of structure `group`.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is not changed; otherwise, an error code.
The PXFGETGRGID subroutine stores the group information from /etc/group for the entry that matches the group GID \( jgid \) in the structure associated with handle \( jgroup \).

**NOTE.** To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

See Also: “PXFSTRUCTCREATE”

Example

See the example in “PXFGETGROUPS”.

**PXFGETGRNAM**

**POSIX Subroutine:** Gets group information for the named group. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFGETGRNAM (name, ilen, jgroup, ierror)
```

- **name** (Input) Character. The name of the group to retrieve information about.
- **ilen** (Input) INTEGER(4). The length of the name string.
- **jgroup** (Input) INTEGER(4). A handle of structure group.
- **ierror** (Output) INTEGER(4). The error status.

If successful, \( ierror \) is not changed; otherwise, an error code.

The PXFGETGRNAM subroutine stores the group information from /etc/group for the entry that matches the group name \( name \) in the structure associated with handle \( jgroup \).

**NOTE.** To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.
See Also: “PXFSTRUCTCREATE”

PXGETGROUPS

POSIX Subroutine: Gets supplementary group IDs. This subroutine is only available on Linux* system and Mac OS* systemss.

Module: USE IFPOSIX

Syntax

CALL PXGETGROUPS (igidsetsize, igrouplist, ngroups, ierror)

igidsetsize
(Input) INTEGER(4). The number of elements in the igrouplist array.

igrouplist
(Output) INTEGER(4). The array that has the returned supplementary group IDs.

ngroups
(Output) INTEGER(4). The total number of supplementary group IDs for the process.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXGETGROUPS subroutine returns, up to size igidsetsize, the supplementary group IDs in array igrouplist. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

Example

program test5
use ifposix
implicit none
integer(4) number_of_groups, ierror, isize, i, igid
integer(4), allocatable, dimension(:): igrouplist
integer(JHANDLE_SIZE) jgroup

! Get total number of groups in system
! call PXGETGROUPS with 0
call PXGETGROUPS(0, igrouplist, number_of_groups, ierror)
if(ierror.NE.0) STOP 'Error: first call of PXGETGROUPS fails'
print *,'The number of groups in system ', number_of_groups

! Get Group IDs
isize = number_of_groups
ALLOCATE( igrouplist(isize))
call PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
if(ierror.NE.0) then
   DEALLOCATE(igrouplist)
   STOP 'Error: first call of PXFGETGROUPS fails'
end if

print *," Create an instance for structure 'group' ",
call PXFSTRUCTCREATE("group",jgroup, ierror)
if(ierror.NE.0) then
   DEALLOCATE(igrouplist)
   STOP 'Error: PXFSTRUCTCREATE failed to create an instance of group'
end if

do i=1, number_of_groups
   call PXFGETGRGID( igrouplist(i), jgroup, ierror)
   if(ierror.NE.0) then
      DEALLOCATE(igrouplist)
      call PXFSTRUCTFREE(jgroup, ierror)
      print *, 'Error: PXFGETGRGID failed for i=',i," gid=", igrouplist(i)
      STOP 'Abnormal termination'
   end if
   call PRINT_GROUP_INFO(jgroup)
end do

call PXFGETGID(igid,ierror)
if(ierror.NE.0) then
   DEALLOCATE(igrouplist)
   call PXFSTRUCTFREE(jgroup, ierror)
   print *, 'Error: PXFGETGID failed' 
   STOP 'Abnormal termination'
end if

call PXFGETGRGID( igid, jgroup, ierror)
if(ierror.NE.0) then
   DEALLOCATE(igrouplist)
   call PXFSTRUCTFREE(jgroup, ierror)
   print *, "Error: PXFGETGRGID failed for gid=", igid
STOP 'Abnormal termination'
end if

call PRINT_GROUP_INFO(jgroup)
DEALLOCATE(igrouplist)
call PXFSTRUCTFREE(jgroup, ierror)
print *," Program will normal terminated"
call PXFEXIT(0)
end

**PXGETLOGIN**

**POSIX Subroutine:** Gets the name of the user.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFGETLOGIN (s, ilen, ierror)
```

- **s**  
  (Output) Character. The returned user name.

- **ilen**  
  (Output) INTEGER(4). The length of the string stored in s.

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero, otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**PXGETPGRP**

**POSIX Subroutine:** Gets the process group ID of the calling process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFGETPGRP (ipgrp, ierror)
```

- **ipgrp**  
  (Output) INTEGER(4). The returned process group ID.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

Each process group is a member of a session and each process is a member of the session in which its process group is a member.

PXFGETPID

**POSIX Subroutine:** Gets the process ID of the calling process.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFGETPID (ipid, ierror)

*ipid*
(Output) INTEGER(4). The returned process ID.

*ierror*
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD  GRAPHICS  QUICKWIN  GRAPHICS  WINDOWS  DLL  LIB

**See Also:** the example in “PXFWAIT”

PXFGETPPID

**POSIX Subroutine:** Gets the process ID of the parent of the calling process.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFGETPPID (ippid, ierror)

*ippid*
(Output) INTEGER(4). The returned process ID.

*ierror*
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also: the example in “PXFWAIT”

PXGETPW

**POSIX Subroutine:** Gets password information for a specified name. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

CALL PXGETPW (name, ilen, jpasswd, ierror)

*name* (Input) Character. The login name of the user to retrieve information about. For example, a login name might be "jsmith", while the actual name is "John Smith".

*ilen* (Input) INTEGER(4). The length of the *name* string.

*jpasswd* (Input) INTEGER(4). A handle of structure `compnam`.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXGETPW subroutine stores the user information from `/etc/passwd` for the entry that matches the user name *name* in the structure associated with handle *jpasswd*.

---

**NOTE.** To get a handle for an instance of the `compnam` structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

See Also: “PXFSTRUCTCREATE”

PXGETPWUID

**POSIX Subroutine:** Gets password information for a specified UID. This subroutine is only available on Linux* systems and Mac OS* systems.
Module: USE IFPOSIX

Syntax

CALL PXFGETPWUID (iuid, jpasswd, ierror)

iuid
(Input) INTEGER(4). The user ID to retrieve information about.

jpasswd
(Input) INTEGER(4). A handle of structure compnam.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The PXFGETPWUID subroutine stores the user information from /etc/passwd for the entry that matches the user ID iuid in the structure associated with handle jpasswd.

NOTE. To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

See Also: "PXFSTRUCTCREATE"

PXFGETSUBHANDLE

POSIX Subroutine: Returns a handle for a subroutine.
Module: USE IFPOSIX

Syntax

CALL PXFGETSUBHANDLE (sub, jhandle1, ierror)

sub
(Input) The Fortran subroutine to get a handle for.

jhandle1
(Output) INTEGER(4). The returned handle for the subroutine.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
PXFGETUID

POSIX Subroutine: Gets the real user ID of the current process. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

CALL PXFGETUID (iuid, ierror)

iuid

(Output) INTEGER(4). The returned real user ID.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

See Also: “PXFSETUID”

PXFISBLK

POSIX Function: Tests for a block special file.

Module: USE IFPOSIX

Syntax

result = PXFISBLK (m)

m

(Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.
Results:
The result type is logical. If the file is a block special file, the result value is .TRUE.; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “PXFISCHR”

PXFISCHR

POSIX Function: Tests for a character file.
Module: USE IFPOSIX
Syntax
  result = PXFISCHR (m)

m
(Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results:
The result type is logical. If the file is a character file, the result value is .TRUE.; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “PXFISBLK”

PXFISCONST

POSIX Function: Tests whether a string is a valid constant name.
Module: USE IFPOSIX
Syntax
  result = PXFISCONST (s)

s
(Input) Character. The name of the constant to test.

Results:
The result type is logical. The PXFISCONST function confirms whether the argument is a valid constant name that can be passed to functions PXFCONST and IPXFCONST. It returns .TRUE. only if IPXFCONST will return a valid value for name s.
PXFISDIR

POSIX Function: Tests whether a file is a directory.
Module: USE IFPOSIX
Syntax
  result = PXFISDIR (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results:
The result type is logical. If the file is a directory, the result value is .TRUE.; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “IPXFCONST”, “PXFCONST”

PXFISFIFO

POSIX Function: Tests whether a file is a special FIFO file.
Module: USE IFPOSIX
Syntax
  result = PXFISFIFO (m)

m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

Results:
The result type is logical.
The PXFISFIFO function tests whether the file is a special FIFO file created by PXFMKFIFO. If the file is a special FIFO file, the result value is .TRUE.; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PXFISREG”, “PXFMKFIFO”
**PXFISREG**

**POSIX Function:** Tests whether a file is a regular file.

**Module:** USE IFPOSIX

**Syntax**

```fortran
result = PXFISREG (m)
```

*m*  
(Input) INTEGER(4). The value of the *st_mode* component (field) in the structure *stat*.

**Results:**

The result type is logical. If the file is a regular file, the result value is .TRUE.; otherwise, .FALSE..

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "PXFISFIFO", "PXFMKFIFO"

---

**PXFKILL**

**POSIX Subroutine:** Sends a signal to a specified process.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFKILL (ipid, isig, ierror)
```

*ipid*  
(Input) INTEGER(4). The process to kill. It is determined by one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>Kills the specific process.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Kills all processes in the group.</td>
</tr>
<tr>
<td>== 0</td>
<td>Kills all processes in the group except special processes.</td>
</tr>
<tr>
<td>== pid_t-1</td>
<td>Kills all processes.</td>
</tr>
</tbody>
</table>

*isig*  
(Input) INTEGER(4). The value of the signal to be sent.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFKILL subroutine sends a signal with value \textit{isig} to a specified process. On Windows* systems, only the \textit{ipid} for the current process can be used.

\textbf{Compatibility}

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

\section*{PXFLINK}

\textbf{POSIX Subroutine:} Creates a link to a file or directory.
\textbf{Module:} USE IFPOSIX
\textbf{Syntax}

\begin{verbatim}
CALL PXFLINK (existing, lenexist, new, lennew, ierror)
\end{verbatim}

existing
(Input) Character. The path to the file or directory you want to link to.

lenexist
(Input) INTEGER(4). The length of the \textit{existing} string.

new
(Input) Character. The name of the new link file.

lennew
(Input) INTEGER(4). The length of the \textit{new} string.

ierror
(Output) INTEGER(4). The error status.

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFLINK subroutine creates a new link (also known as a hard link) to an existing file. This new name can be used exactly as the old one for any operation. Both names refer to the same file (so they have the same permissions and ownership) and it is impossible to tell which name was the "original".

\textbf{NOTE.} \textit{On Windows* systems, this subroutine is only valid for NTFS file systems; for FAT systems, it returns an error.}

\textbf{Compatibility}

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
Descriptions of the Library Routines

PXFLOCALTIME

POSIX Subroutine: Converts a given elapsed time in seconds to local time.

Module: USE IFPOSIX

Syntax

CALL PXFLOCALTIME (isecnds, iatime, ierror)

isecnds

(Input) INTEGER(4). The elapsed time in seconds since 00:00:00 Greenwich Mean Time, January 1, 1970.

iatime

(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of iatime are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>iatime(1)</td>
<td>Seconds (0-59)</td>
</tr>
<tr>
<td>iatime(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>iatime(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>iatime(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>iatime(5)</td>
<td>Month (1-12)</td>
</tr>
<tr>
<td>iatime(6)</td>
<td>Gregorian year (for example, 1990)</td>
</tr>
<tr>
<td>iatime(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>iatime(8)</td>
<td>Day of year (1-366)</td>
</tr>
<tr>
<td>iatime(9)</td>
<td>Daylight savings flag (1 if daylight savings time is in effect; otherwise, 0)</td>
</tr>
</tbody>
</table>

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFLOCALTIME subroutine converts the time (in seconds since epoch) in the isecnds argument to the local date and time as described by the array iatime above.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

PXFLSEEK

POSIX Subroutine: Positions a file a specified distance in bytes.
Module: USE IFPOSIX

Syntax

CALL PXFLSEEK (ifildes, ioffset, iwhence, iposition, ierror)

ifildes
(Input) INTEGER(4). A file descriptor.

ioffset
(Input) INTEGER(4). The number of bytes to move.

iwhence
(Input) INTEGER(4). The starting position. The value must be one of the following:
• SEEK_SET = 0
  Sets the offset to ioffset bytes.
• SEEK_CUR = 1
  Sets the offset to its current location plus ioffset bytes.
• SEEK_END = 2
  Sets the offset to the size of the file plus ioffset bytes.

iposition
(Output) INTEGER(4). The ending position; the resulting offset location as measured in bytes from the beginning of the file.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The PXFLSEEK subroutine repositions the offset of file descriptor ifildes to the argument ioffset according to the value of argument iwhence.
PXFLSEEK allows the file offset to be set beyond the end of the existing end-of-file. If data is later written at this point, subsequent reads of the data in the gap return bytes of zeros (until data is actually written into the gap).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFMKDIR

POSIX Subroutine: Creates a new directory.

Module: USE IFPOSIX
**Syntax**

CALL PXFMKDIR (path, ilen, imode, ierror)

*path*
(Input) Character. The path for the new directory.

*ilen*
(Input) INTEGER(4). The length of *path* string.

*imode* (L*X only)
(Input) INTEGER(4). The mode mask. Octal file-access mode.

*ierror*
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

See Also:  "PXFRMDIR", "PXFCHDIR"

**PXFMKFIFO**

**POSIX Subroutine:** Creates a new FIFO. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFMKFIFO (path, ilen, imode, ierror)

*path*
(Input) Character. The path for the new FIFO.

*ilen*
(Input) INTEGER(4). The length of *path* string.

*imode*
(Input) INTEGER(4). The mode mask; specifies the FIFO's permissions. Octal file-access mode.

*ierror*
(Output) INTEGER(4). The error status.
If successful *ierror* is set to zero; otherwise, an error code.
The PXFMKFIFO subroutine creates a FIFO special file with name path. A FIFO special file is similar to a pipe, except that it is created in a different way. Once a FIFO special file is created, any process can open it for reading or writing in the same way as an ordinary file. However, the FIFO file has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks it until some other process opens the same FIFO for writing, and vice versa.

See Also: “PXFISFIFO”

**PXFOPEN**

**POSIX Subroutine:** Opens or creates a file.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFOPEN (path, ilen, iopenflag, imode, ifildes, ierror)
```

- **path** (Input) Character. The path of the file to be opened or created.
- **ilen** (Input) INTEGER(4). The length of path string.
- **iopenflag** (Input) INTEGER(4). The flags for the file. (For possible constant names that can be passed to PXFCONST or IPXFCONST, see below.)
- **imode** (Input) INTEGER(4). The permissions for a new file. This argument should always be specified when iopenflag = O_CREAT; otherwise, it is ignored. (For possible permissions, see below.)
- **ifildes** (Output) INTEGER(4). The returned file descriptor for the opened or created file.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

For iopenflag, you should specify one of the following constant values:

- O_RDONLY (read only)
- O_WRONLY (write only)
- O_RDWR (read and write)
In addition, you can also specify one of the following constant values by using a bitwise inclusive OR (IOR):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>O_CREAT</td>
<td>Creates and opens a file if the file does not exist.</td>
</tr>
<tr>
<td>O_EXCL</td>
<td>When used with O_CREAT, it causes the open to fail if the file already exists. In this case, a symbolic link exists, regardless of where it points to.</td>
</tr>
<tr>
<td>O_NOCTTY</td>
<td>If <em>path</em> refers to a terminal device, it prevents it from becoming the process’s controlling terminal even if the process does not have one.</td>
</tr>
<tr>
<td>O_TRUNC</td>
<td>If the file already exists, it is a regular file, and <em>imode</em> allows writing (its value is O_RDWR or O_WRONLY), it causes the file to be truncated to length 0.</td>
</tr>
<tr>
<td>O_APPEND</td>
<td>Opens the file in append mode. Before each write, the file pointer is positioned at the end of the file, as if with PXFLSEEK.</td>
</tr>
<tr>
<td>O_NONBLOCK (or O_NDELAY)</td>
<td>When possible, opens the file in non-blocking mode. Neither the open nor any subsequent operations on the file descriptor that is returned will cause the calling process to wait. This mode need not have any effect on files other than FIFOs.</td>
</tr>
<tr>
<td>O_SYNC</td>
<td>Opens the file for synchronous I/O. Any writes on the resulting file descriptor will block the calling process until the data has been physically written to the underlying hardware.</td>
</tr>
<tr>
<td>O_NOFOLLOW</td>
<td>If <em>path</em> is a symbolic link, it causes the open to fail.</td>
</tr>
<tr>
<td>O_DIRECTORY</td>
<td>If <em>path</em> is not a directory, it causes the open to fail.</td>
</tr>
<tr>
<td>O_LARGEFILE</td>
<td>On 32-bit systems that support the Large Files System, it allows files whose sizes cannot be represented in 31 bits to be opened.</td>
</tr>
<tr>
<td>O_BINARY</td>
<td>Opens the file in binary (untranslated) mode.</td>
</tr>
<tr>
<td>O_SHORT_LIVED</td>
<td>Creates the file as temporary. If possible, it does not flush to the disk.</td>
</tr>
<tr>
<td>O_TEMPORARY</td>
<td>Creates the file as temporary. The file is deleted when last file handle is closed.</td>
</tr>
<tr>
<td>O_RANDOM</td>
<td>Specifies primarily random access from the disk.</td>
</tr>
<tr>
<td>O_SEQUENTIAL</td>
<td>Specifies primarily sequential access from the disk.</td>
</tr>
<tr>
<td>O_TEXT</td>
<td>Opens the file in text (translated) mode.</td>
</tr>
</tbody>
</table>

1. L*X only
2. W*32, W*64
3. For more information, see *Text and Binary Modes* in the Visual C++ programmer’s guide.
Argument \textit{imode} specifies the permissions to use if a new file is created. The permissions only apply to future accesses of the newly created file. The value for \textit{imode} can be any of the following constant values (which can be obtained by using PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_IRWXU</td>
<td>00700 user (file owner) has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRUSR, S_IREAD</td>
<td>00400 user has read permission.</td>
</tr>
<tr>
<td>S_IWUSR, S_IWRITE</td>
<td>00200 user has write permission.</td>
</tr>
<tr>
<td>S_IXUSR, S_IEXEC</td>
<td>00100 user has execute permission.</td>
</tr>
<tr>
<td>S_IRWXG\textsuperscript{1}</td>
<td>00070 group has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRGRP\textsuperscript{1}</td>
<td>00040 group has read permission.</td>
</tr>
<tr>
<td>S_IWGRP\textsuperscript{1}</td>
<td>00020 group has write permission.</td>
</tr>
<tr>
<td>S_IXGRP\textsuperscript{1}</td>
<td>00010 group has execute permission.</td>
</tr>
<tr>
<td>S_IROTH\textsuperscript{1}</td>
<td>00007 others have read, write and execute permission.</td>
</tr>
<tr>
<td>S_IWOTH\textsuperscript{1}</td>
<td>00004 others have read permission.</td>
</tr>
<tr>
<td>S_IXOTH\textsuperscript{1}</td>
<td>00001 others have execute permission.</td>
</tr>
</tbody>
</table>

1. L*X only

\textbf{Compatibility}

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\textbf{See Also:} “PXFCLOSE”, “IPXFCONST”, “PXFCONST”

\textbf{Example}

```fortran
    call PXFOPEN( "OPEN.OUT", &
                  8, &
                  IOR( IPXFCONST(O_WRONLY), IPXFCONST(O_CREAT) ), &
                  IOR( IPXFCONST(S_IREAD), IPXFCONST(S_IWRITE) ) )
```

\textbf{PXFOPENDIR}

\textbf{POSIX Subroutine:} Opens a directory and associates a stream with it.

\textbf{Module:} USE IFPOSIX

\textbf{Syntax}

```fortran
    CALL PXFOPENDIR (dirname, lendirname, opendirid, ierror)
```

---

2-316
dirname
(Input) Character. The directory name.

lendirname
(Input) INTEGER(4). The length of dirname string.

opendirid
(Output) INTEGER(4). The returned ID for the directory.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFOPENDIR subroutine opens a directory pointed to by the dirname argument and returns the ID of the directory into opendirid. After the call, this ID can be used by functions PXFREADDR, PXFREWINDDIR, PXFCLOSEDIR.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PXFCLOSEDIR”, “PXFREADDR”, “PXFREWINDDIR”

PXFPATHCONF

POSIX Subroutine: Gets the value for a configuration option of an opened file.
Module: USE IFPOSIX
Syntax
CALL PXFPATHCONF (path, ilen, name, ival, ierror)
path
(Input) Character. The path to the opened file.
ilen
(Input) INTEGER(4). The length of path.
name
(Input) INTEGER(4). The configurable option.
ival
(Input) INTEGER(4). The value of the configurable option.
ierror
(Output) INTEGER(4). The error status.
If successful, \textit{ierror} is set to zero; otherwise, an error code.

The \textbf{PXFPATHCONF} subroutine gets a value for the configuration option named for the opened file with path \textit{path}.

The configuration option, defined in \textit{name}, can be obtained by using \textbf{PXFC\textsc{onst}} or \textbf{IPXFC\textsc{onst}} with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If \textit{path} refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>Returns the maximum length of a formatted input line; the \textit{path} must refer to a terminal</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>Returns the maximum length of an input line; the \textit{path} must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in \textit{path} that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when \textit{path} is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the \textit{path} must refer to a FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>Returns nonzero if PXFC\textsc{chown} may not be used on this file. If \textit{path} refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>Returns nonzero if special character processing can be disabled; the \textit{path} must refer to a terminal.</td>
</tr>
</tbody>
</table>

1. L\textsuperscript{X}, M\textsuperscript{X32}

On Linux\textsuperscript{*} and Mac OS\textsuperscript{*} systems, the corresponding macros are defined in \texttt{<unistd.h>}. The values for \textit{name} can be obtained by using \textbf{PXFC\textsc{onst}} or \textbf{IPXFC\textsc{onst}} when passing the string names of predefined macros in \texttt{<unistd.h>}. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>_POSIX_PATH_MAX</td>
</tr>
</tbody>
</table>
Descriptions of the Library Routines

See Also: “IPXFCONST”, “PXFCONST”, “PXFPATHCONF”

PXFPAUSE

**POSIX Subroutine:** Suspends process execution.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFPAUSE (ierror)
```

**ierror**

(Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFPAUSE subroutine causes the invoking process (or thread) to sleep until a signal is received that either terminates it or causes it to call a signal-catching function.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFPIPE

**POSIX Subroutine:** Creates a communications pipe between two processes.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFPIPE (ireadfd, iwritefd, ierror)
```

**ireadfd**

(Output) INTEGER(4). The file descriptor for reading.

**iwritefd**

(Output) INTEGER(4). The file descriptor for writing.

---

Constants and Corresponding Macros:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>_POSIX_CHOWN_RESTRICTED</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NO_TRUNC</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
</tbody>
</table>
ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. The PXFPIPE subroutine returns a pair of file descriptors, pointing to a pipe inode, and places them into ireadfd for reading and into iwritefd for writing.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**PXFPOSIXIO**

**POSIX Subroutine:** Sets the current value of the POSIX I/O flag.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFPOSIXIO (new, old, ierror)

new

(Input) INTEGER(4). The new value for the POSIX I/O flag.

old

(Output) INTEGER(4). The previous value of the POSIX I/O flag.

ierror

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine sets the current value of the Fortran POSIX I/O flag and returns the previous value of the flag. The initial state of the POSIX I/O flag is unspecified.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is 1, the unit is accessed as if the records are newline delimited, even if the file does not contain records that are delimited by a new line character.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is zero, a connection to a file descriptor is not assumed and the records in the file are not required to be accessed as if they are newline delimited.

Compatibility

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
PXFPUTC

**POSIX Subroutine:** Outputs a character to logical unit 6 (stdout).

**Module:** USE IFPOSIX

**Syntax**

```call
CALL PXFPUTC (ch, ierror)
```

- **ch**
  (Input) Character. The character to be written.

- **ierror**
  (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**See Also:** "PXFGETC"

PXREAD

**POSIX Subroutine:** Reads from a file.

**Module:** USE IFPOSIX

**Syntax**

```call
CALL PXFREAD (ifildes, buf, nbyte, nread, ierror)
```

- **ifildes**
  (Input) INTEGER(4). The file descriptor of the file to be read from.

- **buf**
  (Output) Character. The buffer that stores the data read from the file.

- **nbyte**
  (Input) INTEGER(4). The number of bytes to read.

- **nread**
  (Output) INTEGER(4). The number of bytes that were read.

- **ierror**
  (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFREAD subroutine reads \textit{nbyte} bytes from the file specified by \textit{ifildes} into memory in \textit{buf}. The subroutine returns the total number of bytes read into \textit{nread}. If no error occurs, the value of \textit{nread} will equal the value of \textit{nbyte}.

\textbf{Compatibility}

| CONSOLE | STANDARD | GRAPHICS | QUICKWIN | GRAPHICS | WINDOWS | DLL | LIB |
\end{tabular}

\textbf{See Also:} “\textsc{PXFWRITE}”

\textbf{PXFREADDR}

\textbf{POSIX Subroutine:} Reads the current directory entry.

\textbf{Module:} USE IFPOSIX

\textbf{Syntax}

\begin{verbatim}
CALL PXFREADDR (idirid, jdirent, ierror)
\end{verbatim}

\begin{itemize}
\item \textit{idirid} (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
\item \textit{jdirent} (Output) INTEGER(4). A handle of structure \textit{dirent}.
\item \textit{ierror} (Output) INTEGER(4). The error status.
\end{itemize}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFREADDR subroutine reads the entry of the directory associated with \textit{idirid} into the structure associated with handle \textit{jdirent}.

\textbf{NOTE.} To get a handle for an instance of the \textit{dirent} structure, use PXFSTRUCTCREATE with the string 'dirent' for the structure name.

\textbf{Compatibility}

\begin{tabular}{l}
| CONSOLE | STANDARD | GRAPHICS | QUICKWIN | GRAPHICS | WINDOWS | DLL | LIB |
\end{tabular}

\textbf{See Also:} “\textsc{PXFOPENDIR}”, “\textsc{PXREWINDDIR}”

\textbf{PXFRENAME}

\textbf{POSIX Subroutine:} Changes the name of a file.
Module: USE IFPOSIX
Syntax
   CALL PXFRENAME (old, lenold, new, lennew, ierror)
old
(Input) Character. The name of the file to be renamed.
lenold
(Input) INTEGER(4). The length of old string.
new
(Input) Character. The new file name.
lennew
(Input) INTEGER(4). The length of new string.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
Compatibility
   CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

PXFREWINDDIR

POSIX Subroutine: Resets the position of the stream to the beginning of the directory.
Module: USE IFPOSIX
Syntax
   CALL PXFREWINDDIR (idirid, ierror)
idirid
(Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
Compatibility
   CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
PXFRMDIR

**POSIX Subroutine:** Removes a directory.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFRMDIR (path, ilen, ierror)
```

- `path` *(Input)* Character. The directory to be removed. It must be empty.
- `ilen` *(Input)* INTEGER(4). The length of `path` string.
- `ierror` *(Output)* INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**See Also:** “PXFMKDIR”, “PXFCHDIR”

PXFSETENV

**POSIX Subroutine:** Adds a new environment variable or sets the value of an environment variable.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
```

- `name` *(Input)* Character. The name of the environment variable.
- `lenname` *(Input)* INTEGER(4). The length of `name`.
- `new` *(Input)* Character. The value of the environment variable.
- `lennew` *(Input)* INTEGER(4). The length of `new`.
**ioverwrite**  
(Input) INTEGER(4). A flag indicating whether to change the value of the environment variable if it exists.

**ierror**  
(Output) INTEGER(4). The error status.  
If successful, **ierror** is set to zero; otherwise, an error code.

If **name** does not exist, PXFSETENV adds it with value **new**.

If **name** exists, PXFSETENV sets it’s value to **new** if **ioverwrite** is a nonzero number. If **ioverwrite** is zero, the value of **name** is not changed.

If **lennew** is equal to zero, PXFSETENV sets the value of the environment variable to a string equal to **new** after removing any leading or trailing blanks.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**See Also:** ["PXFGETENV"]

**Example**

```fortran
program test2
use ifposix
character*10 name, new
integer lenname, lennew, ioverwrite, ierror
name = "FOR_NEW"
lenname = 7
new = "ON"
lennew = 2
ioverwrite = 1

CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
print *, "name= ", name
print *, "lenname= ", lenname
print *, "new= ", lenname
print *, "lennew= ", lenname
print *, "ierror= ", ierror
end
```
PXFSETGID

**POSIX Subroutine:** Sets the effective group ID of the current process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFSETGID (igid, ierror)
```

- `igid` (Input) INTEGER(4). The group ID.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

If the caller is the superuser, the real and saved group ID’s are also set. This feature allows a program other than root to drop all of its group privileges, do some un-privileged work, and then re-engage the original effective group ID in a secure manner.

---

**CAUTION.** If the user is root then special care must be taken. PXFSETGID checks the effective gid of the caller. If it is the superuser, all process-related group ID’s are set to gid. After this has occurred, it is impossible for the program to regain root privileges.

---

**See Also:** [“PXFGETGID”](#)

---

PXFSETPGID

**POSIX Subroutine:** Sets the process group ID. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFSETPGID (ipid, ipgid, ierror)
```

- `ipid` (Input) INTEGER(4). The process group ID to change.
- `ipgid` (Input) INTEGER(4). The new process group ID.
ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFSETPGID subroutine sets the process group ID of the process specified by ipid to ipgid.
If ipid is zero, the process ID of the current process is used. If ipgid is zero, the process ID of the
process specified by ipid is used.
PXFSETPGID can be used to move a process from one process group to another, but both process
groups must be part of the same session. In this case, ipgid specifies an existing process group to
be joined and the session ID of that group must match the session ID of the joining process.

**PXFSETSID**

**POSIX Subroutine:** Creates a session and sets the process group ID. This subroutine is only
available on Linux* systems.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFSETSID (isid, ierror)

isid
(Output) INTEGER(4). The session ID.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFSETSID subroutine creates a new session if the calling process is not a process group
leader.
The calling process is the leader of the new session and the process group leader for the new
process group. The calling process has no controlling terminal.
The process group ID and session ID of the calling process are set to the PID of the calling
process. The calling process will be the only process in this new process group and in this new
session.

**PXFSETUID**

**POSIX Subroutine:** Sets the effective user ID of the current process. This subroutine is only
available on Linux* system and Mac OS* systemss.

**Module:** USE IFPOSIX

2-327
Syntax

    CALL PXFSETUID (iuid, ierror)

*iuid*  
(Output) INTEGER(4). The session ID.

*ierror*  
(Output) INTEGER(4). The user status.

If successful, *ierror* is set to zero; otherwise, an error code.

If the effective user ID of the caller is root, the real and saved user ID’s are also set. This feature
allows a program other than root to drop all of its user privileges, do some un-privileged work, and
then re-engage the original effective user ID in a secure manner.

---

**CAUTION.** If the user is root then special care must be taken. PXFSETUID checks the effective uid of the caller. If it is the superuser, all process-related user ID’s are set to uid. After this has occurred, it is impossible for the program to regain root privileges.

See Also: "PXFGETUID"

**PXFSIGACTION**

**POSIX Subroutine:** Changes the action associated with a specific signal. It can also be used to examine the action of a signal.

**Module:** USE IFPOSIX

**Syntax**

    CALL PXFSIGACTION (isig, jsigact, josigact, ierror)

*isig*  
(Input) INTEGER(4). The signal number whose action should be changed.

[jsigact]  
(Input) INTEGER(4). A handle of structure *sigaction*. Specifies the new action for signal *isig*.

[josigact]  
(Output) INTEGER(4). A handle of structure *sigaction*. Stores the previous action for signal *isig*. 
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The signal specified in *isig* can be any valid signal except SIGKILL and SIGSTOP.

If *jsigact* is nonzero, the new action for signal *isig* is installed from the structure associated with handle *jsigact*. If *josigact* is nonzero, the previous action of the specified signal is saved in the structure associated with handle *josigact* where it can be examined.

On Windows* systems, PXFSIGACTION ignores the fields sa_mask and sa_flags in structure sigaction.

---

**NOTE.** To get a handle for an instance of the sigaction structure, use PXFSTRUCTCREATE with the string 'sigaction' for the structure name.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “PXFSTRUCTCREATE”

---

**PXFSIGADDSET**

**POSIX Subroutine:** Adds a signal to the signal set. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```plaintext
CALL PXFSIGADDSET (jsigset, isigno, ierror)
```

- **jsigset**
  (Input) INTEGER(4). A handle of structure sigset. This is the set to add the signal to.

- **isigno**
  (Input) INTEGER(4). The signal number to add to the set.

- **ierror**
  (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFSIGADDSET subroutine adds signal number \textit{isigno} to the set of signals associated with handle \textit{jsigset}. This set of signals is used by PXFSIGACTION as field \textit{sa\_mask} in structure \textit{sigaction}. It defines the set of signals that will be blocked during execution of the signal handler function (the field \textit{sa\_handler} in structure \textit{sigaction}).

On Windows* systems, PXFSIGACTION ignores the field \textit{sa\_mask} in structure \textit{sigaction}.

\begin{note}
\textbf{NOTE.} To get a handle for an instance of the \textit{sigset} structure, use \texttt{PXFSSTRUCTCREATE} with the string \texttt{'sigset'} for the structure name.
\end{note}

\textbf{See Also:} \texttt{"PXFSSTRUCTCREATE"}, \texttt{"PXFSIGDELSET"}, \texttt{"PXFSIGACTION"}

\textbf{PXFSIGDELSET}

\textbf{POSIX Subroutine:} Deletes a signal from the signal set. This subroutine is only available on Linux* systems and Mac OS* systems.

\textbf{Module:} USE IFPOSIX

\textbf{Syntax}

\begin{verbatim}
CALL PXFSIGDELSET (jsigset, isigno, ierror)
\end{verbatim}

\begin{itemize}
  \item \textit{jsigset} (Input) INTEGER(4). A handle of structure \textit{sigset}. This is the set to delete the signal from.
  \item \textit{isigno} (Input) INTEGER(4). The signal number to delete from the set.
  \item \textit{ierror} (Output) INTEGER(4). The error status.
\end{itemize}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFSIGDELSET subroutine removes signal number \textit{isigno} from the set of signals associated with handle \textit{jsigset}. This set of signals is used by PXFSIGACTION as field \textit{sa\_mask} in structure \textit{sigaction}. It defines the set of signals that will be blocked during execution of the signal handler function (the field \textit{sa\_handler} in structure \textit{sigaction}).

On Windows* systems, PXFSIGACTION ignores the field \textit{sa\_mask} in structure \textit{sigaction}. 
NOTE. To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFSIGADDSET”, “PXFSIGACTION”

PXFSIGEMPTYSET

**POSIX Subroutine:** Empties a signal set. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFSIGEMPTYSET (jsigset, ierror)
```

*jsigset* (Input) INTEGER(4). A handle of structure *sigset*. This is the set to empty.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, nonzero.

The PXFSIGEMPTYSET subroutine initializes the signal set associated with handle *jsigset* to empty; all signals are excluded from the set. This set of signals is used by PXFSIGACTION as field *sa_mask* in structure *sigaction*. It defines the set of signals that will be blocked during execution of the signal handler function (the field *sa_handler* in structure *sigaction*).

On Windows* systems, PXFSIGACTION ignores the field *sa_mask* in structure *sigaction*.

NOTE. To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFSIGFILLSET”, “PXFSIGACTION”

PXFSIGFILLSET

**POSIX Subroutine:** Fills a signal set. This subroutine is only available on Linux* systems and Mac OS* systems.

NOTE. To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.
Module:  USE IFPOSIX

Syntax

CALL PXFSIGFILLSET (jsigset, ierror)

jsigset
(Input) INTEGER(4). A handle of structure sigset. This is the set to fill.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGFILLSET subroutine initializes the signal set associated with handle jsigset to full; all
signals are included into the set. This set of signals is used by PXFSIGACTION as field sa_mask
in structure sigaction. It defines the set of signals that will be blocked during execution of the
signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

NOTE. To get a handle for an instance of the sigset structure, use
PXFSTRUCTCREATE with the string 'sigset' for the structure name.

See Also:  “PXFSTRUCTCREATE”, “PXFSIGEMPTYSET”, “PXFSIGACTION”

PXFSIGISMEMBER

POSIX Subroutine:  Tests whether a signal is a member of a signal set. This subroutine is only
available on Linux* systems and Mac OS* systems.

Module:  USE IFPOSIX

Syntax

CALL PXFSIGISMEMBER (jsigset, isigno, ismember, ierror)

jsigset
(Input) INTEGER(4). A handle of structure sigset. This is the set the signal will be tested in.

isigno
(Input) INTEGER(4). The signal number to test for membership.

ismember
(Output) Logical. The returned result.
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGISMEMBER subroutine tests whether *isigno* is a member of the set associated with handle *jsigset*. If the signal is a member of the set, *ismember* is set to .TRUE.; otherwise, .FALSE.. This set of signals is used by PXFSIGACTION as field sa_mask in structure *sigaction*. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure *sigaction*).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure *sigaction*.

---

**NOTE. To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.**

See Also: “PXFSTRUCTCREATE”, “PXFSIGACTION”

**PXFSIGPENDING**

**POSIX Subroutine:** Examines pending signals. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFSIGPENDING (jsigset, ierror)
```

*jsigset*  
(Input) INTEGER(4). A handle of structure *sigaction*. The signals to examine.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGPENDING subroutine is used to examine pending signals (ones that have been raised while blocked). The signal mask of the pending signals is stored in the signal set associated with handle *jsigset*. 

---

2-333
**PXFSIGPROCMASK**

**POSIX Subroutine:** Changes the list of currently blocked signals. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFSIGPROCMASK (ihow, jsigset, josigset, ierror)
```

- **ihow**
  (Input) INTEGER(4). Defines the action for `jsigset`.

- **jsigset**
  (Input) INTEGER(4). A handle of structure `sigset`. The signals to examine.

- **josigset**
  (Input) INTEGER(4). A handle of structure `sigset`. Stores the previous mask of blocked signals.

- **ierror**
  (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The argument `ihow` indicates the way in which the set is to be changed, and consists of one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIG_BLOCK</td>
<td>The resulting set of blocked signals will be the union of the current signal set and the <code>jsigset</code> signal set.</td>
</tr>
<tr>
<td>SIG_UNBLOCK</td>
<td>The resulting set of blocked signals will be the current set of blocked signals with the signals in <code>jsigset</code> removed. It is legal to attempt to unblock a signal that is not blocked.</td>
</tr>
<tr>
<td>SIG_SETMASK</td>
<td>The resulting set of blocked signals will be the <code>jsigset</code> signal set.</td>
</tr>
</tbody>
</table>

1. These names can be used in PXFCONST or IPXFCONST.

If `josigset` is non-zero, the previous value of the signal mask is stored in the structure associated with handle `josigset`.

**See Also:** [“IPXFCONST”](#), [“PXFCONST”](#)
**PXFSIGSUSPEND**

**POSIX Subroutine:** Suspend the process until a signal is received. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFSIGSUSPEND (jsigset, ierror)
```

- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

PXFSIGSUSPEND temporarily replaces the signal mask for the process with that given by the structure associated with the `jsigset` handle; it then suspends the process until a signal is received.

**PXFSLEEP**

**POSIX Subroutine:** Forces the process to sleep.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFSLEEP (iseconds, isecleft, ierror)
```

- `iseconds` (Input) INTEGER(4). The number of seconds to sleep.
- `isecleft` (Output) INTEGER(4). The number of seconds left to sleep.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFSLEEP subroutine forces the current process to sleep until seconds `iseconds` have elapsed or a signal arrives that cannot be ignored.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFSTAT**

**POSIX Subroutine:** Gets a file's status information.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFSTAT (path, ilen, jstat, ierror)

*path*  
(Input) Character. The path to the file.

*ilen*  
(Input) INTEGER(4). The length of *path* string.

*jstat*  
(Input) INTEGER(4). A handle of structure *stat*.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSTAT subroutine puts the status information for the file specified by *path* into the structure associated with handle *jstat*.

---

**NOTE.** *To get a handle for an instance of the *stat* structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.*

---

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**See Also:** “PXFSTRUCTCREATE”

---

**PXFSTRUCTCOPY**

**POSIX Subroutine:** Copies the contents of one structure to another.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFSTRUCTCOPY (structname, jhandle1, jhandle2, ierror)

*structname*  
(Input) Character. The name of the structure.
Descriptions of the Library Routines

jhandle1
(Input) INTEGER(4). A handle to the structure to be copied.

jhandle2
(Input) INTEGER(4). A handle to the structure that will receive the copy.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
See the example in “PXFSTRUCTCREATE”.

PXFSSTRUCTCREATE

POSIX Subroutine: Creates an instance of the specified structure.

Module: USE IFPOSIX

Syntax
CALL PXFSSTRUCTCREATE (structname, jhandle, ierror)

structname
(Input) Character. The name of the structure.
As for any character string, the name must be specified in single or double quotes; for example, the structure sigaction would be specified as 'sigaction'. (For more information on available structures, see the table below.)

jhandle
(Output) INTEGER(4). The handle of the newly-created structure.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

If your application passes information to the system, you should call one of the PXF<TYPE>SET subroutines. If your application needs to get information from the structure, you should call one of the PXF<TYPE>GET subroutines.

The following table shows:
- The structures that are available in the Fortran POSIX library

---

2-337
The fields within each structure
The subroutines you must use to access the structure fields

The subroutine needed to access the field may depend on whether you are using an IA-32 processor or Intel Itanium processor. In these cases, the subroutine is labeled as i32 or i64, respectively, in the table:

call PXFEXIT(0)
end

**PXFSTRUCTFREE**

**POSIX Subroutine:** Deletes the instance of a structure.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFSTRUCTFREE (jhandle, ierror)

jhandle
(Input) INTEGER(4). A handle of a structure.

ierror
(Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSTRUCTFREE subroutine deletes the instance of the structure associated with handle *jhandle*.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
Example

See the example in “PXFSTRUCTCREATE”, the example in “PXFTIMES”.

**PXFSYSCONF**

**POSIX Subroutine:** Gets values for system limits or options.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFSYSCONF (name, ival, ierror)
```

- **name**
  (Input) INTEGER(4). The system option you want information about.

- **ival**
  (Output) INTEGER(4). The returned value.

- **ierror**
  (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

*PXFSYSCONF* lets you determine values for system limits or system options at runtime.

The value for *name* can be any of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SC_ARG_MAX&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Indicates the maximum length of the arguments to the PXFEXEC family of routines.</td>
</tr>
<tr>
<td>_SC_CHILD_MAX&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Indicates the number of simultaneous processes per user ID.</td>
</tr>
<tr>
<td>_SC_CLK_TCK</td>
<td>Indicates the number of clock ticks per second.</td>
</tr>
<tr>
<td>_SC_STREAM_MAX&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Indicates the maximum number of streams that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_TZNAME_MAX</td>
<td>Indicates the maximum number of bytes in a timezone name.</td>
</tr>
<tr>
<td>_SC_OPEN_MAX</td>
<td>Indicates the maximum number of files that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_JOB_CONTROL&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Indicates whether POSIX-style job control is supported.</td>
</tr>
<tr>
<td>_SC_SAVED_IDS&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Indicates whether a process has a saved set-user-ID and a saved set-group-ID.</td>
</tr>
<tr>
<td>_SC_VERSION&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Indicates the year and month the POSIX.1 standard was approved in the format YYYYMM; the value 199009L indicates the most recent revision, 1990.</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>_SC_BC_BASE_MAX</td>
<td>Indicates the maximum obase value accepted by the bc(1) utility.</td>
</tr>
<tr>
<td>_SC_BC_DIM_MAX</td>
<td>Indicates the maximum value of elements that bc(1) permits in an array.</td>
</tr>
<tr>
<td>_SC_BC_SCALE_MAX</td>
<td>Indicates the maximum scale value allowed by bc(1).</td>
</tr>
<tr>
<td>_SC_BC_STRING_MAX</td>
<td>Indicates the maximum length of a string accepted by bc(1).</td>
</tr>
<tr>
<td>_SC_COLL_WEIGHTS_MAX</td>
<td>Indicates the maximum numbers of weights that can be assigned to an entry of the LC_COLLATE order keyword in the locale definition file.</td>
</tr>
<tr>
<td>_SC_EXPR_NEST_MAX</td>
<td>Indicates the maximum number of expressions that can be nested within parentheses by expr(1).</td>
</tr>
<tr>
<td>_SC_LINE_MAX</td>
<td>Indicates the maximum length of a utility's input line length, either from standard input or from a file. This includes the length for a trailing newline.</td>
</tr>
<tr>
<td>_SC_RE_DUP_MAX</td>
<td>Indicates the maximum number of repeated occurrences of a regular expression when the interval notation {m,n} is used.</td>
</tr>
<tr>
<td>_SC_2_VERSION</td>
<td>Indicates the version of the POSIX.2 standard; it is in the format YYYYMM.</td>
</tr>
<tr>
<td>_SC_2_DEV</td>
<td>Indicates whether the POSIX.2 C language development facilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_DEV</td>
<td>Indicates whether the POSIX.2 FORTRAN language development utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_RUN</td>
<td>Indicates whether the POSIX.2 FORTRAN runtime utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_LOCALEDEF</td>
<td>Indicates whether the POSIX.2 creation of locates via localedef(1) is supported.</td>
</tr>
<tr>
<td>_SC_2_SW_DEV</td>
<td>Indicates whether the POSIX.2 software development utilities option is supported.</td>
</tr>
<tr>
<td>_SC_PAGESIZE (or _SC_PAGE_SIZE)</td>
<td>Indicates the size of a page (in bytes).</td>
</tr>
<tr>
<td>_SC_PHYS_PAGES</td>
<td>Indicates the number of pages of physical memory. Note that it is possible for the product of this value and the value of _SC_PAGE_SIZE to overflow.</td>
</tr>
<tr>
<td>_SC_AVPHYS_PAGES</td>
<td>Indicates the number of currently available pages of physical memory.</td>
</tr>
</tbody>
</table>

1. L*X only
2. The corresponding POSIX macro is STREAM_MAX.
3. The corresponding POSIX macro is EXPR_NEST_MAX.
4. L*X, W*32, W*64
The corresponding macros are defined in \texttt{<bits/confname.h>} on Linux* systems; \texttt{<unistd.h>} on Mac OS* systems. The values for argument \textit{name} can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in the appropriate .h file.

\begin{description}
\item[\textbf{PXFTCDRAIN}] \textbf{POSIX Subroutine}: Waits until all output written has been transmitted. This subroutine is only available on Linux* systems and Mac OS* systems.
\item[\textbf{Module}: USE IFPOSIX]
\item[\textbf{Syntax}]
\begin{verbatim}
CALL PXFTCDRAIN (ifildes, ierror)
\end{verbatim}
\item[\textit{ifildes}] (Input) INTEGER(4). The file descriptor associated with the terminal.
\item[\textit{ierror}] (Output) INTEGER(4). The error status.
\end{description}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

\begin{description}
\item[\textbf{PXFTCFLOW}] \textbf{POSIX Subroutine}: Suspends the transmission or reception of data. This subroutine is only available on Linux* systems and Mac OS* systems.
\item[\textbf{Module}: USE IFPOSIX]
\item[\textbf{Syntax}]
\begin{verbatim}
CALL PXFTCFLOW (ifildes, iaction, ierror)
\end{verbatim}
\item[\textit{ifildes}] (Input) INTEGER(4). The file descriptor associated with the terminal.
\item[\textit{iaction}] (Input) INTEGER(4). The action to perform.
\item[\textit{ierror}] (Output) INTEGER(4). The error status.
\end{description}

If successful, \textit{ierror} is set to zero; otherwise, an error code.
The PXFTCFLOW subroutine suspends or resumes transmission or reception of data from the terminal referred to by `ifildes`. The action performed depends on the value of `iaction`, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCOOFF</td>
<td>Output is suspended.</td>
</tr>
<tr>
<td>TCOON</td>
<td>Output is resumed.</td>
</tr>
<tr>
<td>TCIOFF</td>
<td>A STOP character is transmitted. This should cause the terminal to stop transmitting data to the system.</td>
</tr>
<tr>
<td>TCION</td>
<td>A START character is transmitted. This should cause the terminal to resume transmitting data to the system.</td>
</tr>
</tbody>
</table>

1. These names can be used in PXFCNST or IPXFCNST.

**See Also:** “IPXFCNST”, “PXFCNST”

### PXFTCFLUSH

**POSIX Subroutine:** Discards terminal input data, output data, or both. This subroutine is only available on Linux® systems and Mac OS® systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFTCFLUSH (ifildes, iaction, ierror)
```

ifildes
(Input) INTEGER(4). The file descriptor associated with the terminal.

iaction
(Input) INTEGER(4). The action to perform.

ierror
(Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The action performed depends on the value of `iaction`, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCIFLUSH</td>
<td>Discards all data that has been received but not read.</td>
</tr>
<tr>
<td>TCOFLUSH</td>
<td>Discards all data that has been written but not transmitted.</td>
</tr>
</tbody>
</table>
PXFTCGETATTR

POSIX Subroutine: Returns current terminal settings. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

CALL PXFTCGETATTR (ifildes, jtermios, ierror)

ifildes
(Input) INTEGER(4). The file descriptor associated with the terminal.

jtermios
(Output) INTEGER(4). A handle for structure termios. Stores the terminal settings.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE. To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFTCSETATTR”

PXFTCGETPGRP

POSIX Subroutine: Gets the foreground process group ID associated with the terminal. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

CALL PXFTCGETPGRP (ifildes, ipgid, ierror)
**ifildes**  
(Input) INTEGER(4). The file descriptor associated with the terminal.

**ipgid**  
(Output) INTEGER(4). The returned process group ID.

**ierror**  
(Output) INTEGER(4). The error status.  
If successful, *ierror* is set to zero; otherwise, an error code.

**See Also:** “PXFTCSETPGRP”

---

**PXFTCSENDBREAK**

**POSIX Subroutine:** Sends a break to the terminal. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFTCSENDBREAK (ifildes, iduration, ierror)
```

**ifildes**  
(Input) INTEGER(4). The file descriptor associated with the terminal.

**iduration**  
(Input) INTEGER(4). Indicates how long the break should be.

**ierror**  
(Output) INTEGER(4). The error status.  
If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCSENDBREAK subroutine sends a break (a ‘\0’ with a framing error) to the terminal associated with *ifildes*.

---

**PXFTCSETATTR**

**POSIX Subroutine:** Creates new terminal settings. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```
CALL PXFTCSETATTR (ifildes, ioptacts, jtermios, ierror)
```
ifildes
(Input) INTEGER(4). The file descriptor associated with the terminal.

ioptacts
(Input) INTEGER(4). Specifies when the terminal changes take effect.

jtermios
(Input) INTEGER(4). A handle for structure termios. Contains the new terminal settings.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTCSETATTR subroutine copies all terminal parameters from structure termios into the terminal associated with ifildes. When the terminal settings will change depends on the value of ioptacts, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCSANOW</td>
<td>The changes occur immediately.</td>
</tr>
<tr>
<td>TCSADRAIN</td>
<td>The changes occur after all output written to ifildes has been transmitted.</td>
</tr>
<tr>
<td>TCSAFLUSH</td>
<td>The changes occur after all output written to ifildes has been transmitted, and all input that had been received but not read has been discarded.</td>
</tr>
</tbody>
</table>

1. These names can be used in PXFCONST or IPXFCONST.

NOTE. To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also: “PXFSTRUCTCREATE”, “PXFTCGETATTR”

PXFTCSETPGRP

POSIX Subroutine: Sets the foreground process group ID associated with the terminal. This subroutine is only available on Linux* systems and Mac OS* systems.

Module: USE IFPOSIX

Syntax

CALL PXFTCSETPGRP (ifildes, ipgid, ierror)
ifildes
(Input) INTEGER(4). The file descriptor associated with the terminal.

ipgid
(Input) INTEGER(4). The foreground process group ID for ifildes.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

See Also: “PXFTCGETPGRP”

PXFTIME

POSIX Subroutine: Returns the current system time.
Module: USE IFPOSIX
Syntax
   CALL PXFTIME (itime, ierror)

itime
(Output) INTEGER(4). The returned system time.

ierror
(Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
The PXFTIME subroutine returns the number of seconds since Epoch (00:00:00 UTC, January 1, 1970).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
See the example in “PXFTIMES”.

PXFTIMES

POSIX Subroutine: Returns process times.
Module: USE IFPOSIX
Syntax
   CALL PXFTIMES (jtm, itime, ierror)
The PXFTIMES subroutine fills the fields of structure `tms` associated with handle `jtms` with components of time that was spent by the current process. The structure fields are:

- `tms_utime` – User CPU time
- `tms_stime` – System CPU time
- `tms_cutime` – User time of child process
- `tms_cstime` – System time of child process

All members are measured in system clocks. The values can be converted to seconds by dividing by value `ival` returned from the following call:

```
PXFSYSCONF(IPXFCNST('_SC_CLK_TCK'), ival, ierror)
```

User time is the time charged for the execution of user instructions of the calling process. System time is the time charged for execution by the system on behalf of the calling process.

**NOTE.** To get a handle for an instance of the `tms` structure, use `PXFSTRUCTCREATE` with the string 'tms' for the structure name.

**Compatibility**

PXFTTYNAM

**POSIX Subroutine:** Gets the terminal pathname. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFTTYNAM (ifildes, s, ilen, ierror)
```

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **s** (Output) Character. The returned terminal pathname.
- **ilen** (Output) INTEGER(4). The length of the string stored in s.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero, otherwise, an error code.

PXFUCOMPARE

**POSIX Subroutine:** Compares two unsigned integers.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFUCOMPARE (i1, i2, icmpr, idiff)
```

- **i1**, **i2** (Input) INTEGER(4). The two unsigned integers to compare.
- **icmpr** (Output) INTEGER(4). The result of the comparison; one of the following values:
  - -1 if *i1* < *i2*
  - 0 if *i1* = *i2*
idiff
(Output) INTEGER(4). The absolute value of the difference.
The PXFUCOMPARE subroutine compares two unsigned integers and returns the absolute value of their difference into idiff.

**Compatibility**
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

---

**PXFUMASK**

**POSIX Subroutine:** Sets a new file creation mask and gets the previous one.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFUMASK (icmask, iprevcmask, ierror)
```

- **icmask**
  (Input) INTEGER(4). The new file creation mask.

- **iprevcmask**
  (Output) INTEGER(4). The previous file creation mask.

- **ierror**
  (Output) INTEGER(4). The error status.

  If successful, ierror is set to zero; otherwise, an error code.

**Compatibility**
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

---

**PXFUNAME**

**POSIX Subroutine:** Gets the operation system name.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFUNAME (jutsname, ierror)
```

- **jutsname**
  (Input) INTEGER(4). A handle of structure utsname.

**Compatibility**
CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFUNAME subroutine provides information about the operation system. The information is stored in the structure associated with handle *jutsname*.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

**Example**

See the example in “PXFSTRUCTCREATE”

---

**PXFUNLINK**

**POSIX Subroutine:** Removes a directory entry.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFUNLINK  (path, ilen, ierror)

**path**

(Input) Character. The name of the directory entry to remove.

**ilen**

(Input) INTEGER(4). The length of *path* string.

**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

---

**PXFUTIME**

**POSIX Subroutine:** Sets file access and modification times.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFUTIME  (path, ilen, jutimbuf, ierror)
**path**  
(Input) Character. The path to the file.

**ilen**  
(Input) INTEGER(4). The length of path string.

**jutimbuf**  
(Input) INTEGER(4). A handle of structure utimbuf.

**ierror**  
(Output) INTEGER(4). The error status.  
If successful, ierror is set to zero; otherwise, an error code.

The PXFUTURE subroutine sets access and modification times for the file pointed to by path. The time values are retrieved from structure utimbuf.

**Compatibility**

CONSOLE  STANDARD GRAPHICS  QUICKWIN GRAPHICS  WINDOWS  DLL  LIB

---

**PXFWAIT**

**POSIX Subroutine:** Waits for a child process. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

CALL PXFWAIT (istat, iretpid, ierror)

**istat**  
(Output) INTEGER(4). The returned status of the child process.

**iretpid**  
(Output) INTEGER(4). The process ID of the stopped child process.

**ierror**  
(Output) INTEGER(4). The error status.  
If successful, ierror is set to zero; otherwise, an error code.

The PXFWAIT subroutine suspends execution of the current process until a child has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.
The subroutine returns in `iretpid` the value of the process ID of the child that exited, or zero if no child was available. The returned value in `istat` can be used in subroutines IPXFLEXITSTATUS, IPXFWSTOPSIG, IPXFTERMSIG, PXWIFEXITED, PXWIFSIGNALED, and PXWIFSTOPPED.

**See Also:**  "PXFWAITPID", "IPXFLEXITSTATUS", "IPXFWSTOPSIG", "IPXFTERMSIG", "PXWIFEXITED", "PXWIFSIGNALED", "PXWIFSTOPPED"

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if (IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
   call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," Now I am waiting for the end of the child process"
   call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
   if ( PXWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFLEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program
```
PXFWAITPID

**POSIX Subroutine:** Waits for a specific PID. This subroutine is only available on Linux systems and Mac OS systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXFWAITPID (ipid, istat, ioptions, iretpid, ierror)
```

**ipid**

(Input) INTEGER(4). The PID to wait for. One of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; −1</td>
<td>Specifies to wait for any child process whose process group ID is equal to the absolute value of ipid.</td>
</tr>
<tr>
<td>−1</td>
<td>Specifies to wait for any child process; this is the same behavior as PXFWAIT.</td>
</tr>
<tr>
<td>0</td>
<td>Specifies to wait for any child process whose process group ID is equal to that of the calling process.</td>
</tr>
<tr>
<td>&gt; 0</td>
<td>Specifies to wait for the child whose process ID is equal to the value of ipid.</td>
</tr>
</tbody>
</table>

**istat**

(Output) INTEGER(4). The returned status of the child process.

**ioptions**

(Input) INTEGER(4). One or more of the following constant values (which can be passed to PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WNOHANG</td>
<td>Specifies to return immediately if no child process has exited.</td>
</tr>
<tr>
<td>WUNTRACED</td>
<td>Specifies to return for child processes that have stopped, and whose status has not been reported.</td>
</tr>
</tbody>
</table>

**iretpid**

(Output) INTEGER(4). The PID of the stopped child process.

**ierror**

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFWAITPID subroutine suspends execution of the current process until the child specified by ipid has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child specified by ipid has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The returned value in istat can be used in subroutines IPXFEXITSTATUS, IPXFSTOPSIG, IPXFTERMMSG, PXWEXITED, PXWSIGNALLED, and PXWIFSTOPPED.

See Also: “PXFWAIT”, “IPXFEXITSTATUS”, “IPXFSTOPSIG”, “IPXFTERMMSG”, “PXWEXITED”, “PXWSIGNALLED”, “PXWIFSTOPPED”

PXWEXITED

**POSIX Function:** Determines if a child process has exited. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
result = PXWEXITED (istat)
```

**istat**

(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results:**

The result type is logical. The result value is .TRUE. if the child process has exited normally; otherwise, .FALSE..

See Also: “PXWSIGNALLED”, “PXWIFSTOPPED”

**Example**

```fortran
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET, IERROR)
   print *," The pid of my parent is", IPID_RET
```

print "," Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
print "," I am a parent process"
print "," My parent pid is ", IPID_RET
print "," I am creating the process with pid", IPID
print "," Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
print "," The child with pid ",, IPID_RET," has exited"
if( PXFWIFEXITED(ISTAT) ) then
  print ",, " The child exited normally"
  istat_ret = IPXFWEXITSTATUS(ISTAT)
  print 10," The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

PXFWIFSIGNALED

**POSIX Function:** Determines if a child process has exited because of a signal. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

\[
\text{result} = \text{PXFWIFSIGNALED} (\text{istat})
\]

**istat**

(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results:**

The result type is logical. The result value is .TRUE. if the child process has exited because of a signal that was not caught; otherwise, .FALSE..

**See Also:** “PXFWIFEXITED”, “PXFWIFSTOPPED”
PXFWIFSTOPPED

**POSIX Function:** Determines if a child process has stopped. This subroutine is only available on Linux* systems and Mac OS* systems.

**Module:** USE IFPOSIX

**Syntax**

```fortran
result = PXFWIFSTOPPED (istat)
```

*istat*(Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results:**
The result type is logical. The result value is .TRUE. if the child process has stopped; otherwise, .FALSE..

**See Also:** “PXFWIFEXITED”, “PXFWIFSIGNALED”

PXWRITE

**POSIX Subroutine:** Writes to a file.

**Module:** USE IFPOSIX

**Syntax**

```fortran
CALL PXWRITE (ifildes, buf, nbyte, nwritten, ierror)
```

*ifildes*(Input) INTEGER(4). The file descriptor to be written to.

*buf*(Input) Character. The buffer that contains the data to write into the file.

*nbyte*(Input) INTEGER(4). The number of bytes to write.

*nwritten*(Output) INTEGER(4). The returned number of bytes written.

*ierror*(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.
The PXFWRITE subroutine writes \( nbyte \) bytes from the storage \( buf \) into a file specified by file descriptor \( ifildes \). The subroutine returns the total number of bytes read into \( nwritten \). If no error occurs, the value of \( nwritten \) will equal the value of \( nbyte \).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PXREAD”

**QRANSET**

**Portability Subroutine:** Sets the seed for a sequence of pseudo-random numbers.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL QRANSET (rseed)
```

\( rseed \) (Input) INTEGER(4). The reset value for the seed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**QSORT**

**Portability Subroutine:** Performs a quick sort on an array of rank one.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL QSORT (array, len, isize, compar)
```

\( array \) (Input) Any type. One-dimensional array to be sorted.

If the data type does not conform to one of the predefined interfaces for QSORT, you may have to create a new interface (see the Note below).

\( len \) (Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Number of elements in \( array \).

\( isize \) (Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Size, in bytes, of a single element of \( array \) is:
• 4 if array is of type REAL(4)
• 8 if array is of type REAL(8) or complex
• 16 if array is of type COMPLEX(8)

compar
(Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of compar takes the form:

INTEGER(2) FUNCTION compar (arg1, arg2)

where arg1 and arg2 have the same type as array (above). Once you have created an ordering scheme, implement your sorting function so that it returns the following:
• Negative if arg1 should precede arg2
• Zero if arg1 is equivalent to arg2
• Positive if arg1 should follow arg2

Dummy argument compar must be declared as external.

In place of an INTEGER kind, you can specify the constant SIZEOF_SIZE_T, defined in IFPORT.F90, for argument len or isize. Use of this constant ensures correct compilation.

NOTE. If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module’s source file, IFPORT.F90.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
PROGRAM SORTQ
  USE IFPORT
  integer(2), external :: cmp_function
  integer(2) insort(26), i
  integer (SIZEOF_SIZE_T) array_len, array_size
  array_len = 26
  array_size = 2
  do i=90,65,-1
insort(i-64)=91 - i
end do
print *, "Before: ", insort
CALL qsort(insort,array_len,array_size,cmp_function)
print *, 'After: ', insort
END
!
integer(2) function cmp_function(a1, a2)
integer(2) a1, a2
cmp_function=a1-a2
end function

RAISEQQ

Portability Function: Sends a signal to the executing program.
Module: USE IFPORT
Syntax
result = RAISEQQ(sig)
sig
(Input) INTEGER(4). Signal to raise. One of the following constants (defined in IFPORT.F90):
• SIG$ABORT – Abnormal termination
• SIG$FPE – Floating-point error
• SIG$ILL – Illegal instruction
• SIG$INT – CTRL+C signal
• SIG$SEGV – Illegal storage access
• SIG$TERM – Termination request
If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.
If a signal-handling routine for sig has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SIGNALQQ”, “SIGNAL”, “KILL”

Example
See the example in “SIGNALQQ”.

RAND, RANDOM

Portability Functions: Return real random numbers in the range 0.0 through 1.0.

Module: USE IFPORT

Syntax
result = RAND ([iflag])
result = RANDOM (iflag)

iflag
(Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

Results:
The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 through 1.0.

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection Process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

When RAND is called without an argument, iflag is assumed to be 0.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them. The intrinsic functions RANDOM_NUMBER and RANDOM_SEED provide the same functionality.

You can use SRAND to restart the pseudorandom number generator used by RAND.

NOTE. RANDOM is available as a function or subroutine.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “RANDOM”, “SRAND”, the RANDOM_NUMBER and RANDOM_SEED intrinsic subroutines in the Language Reference

Example
The following example shows how to use both the RANDOM function and the RANDOM subroutine:

```fortran
use ifport
real(4) ranval  !from libifcore.lib
! with libifcore.lib
call seed(1995) ! initialize  !also from for_m_irand.c in libfor
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number
print *,ranval
!from libifport.lib
ranval = random(1)  ! initialize
! same
ranval = random(0)  ! get next random number
print *,ranval
end
```

RANDOM

Portability Subroutine: Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.

Module: USE IFPORT

Syntax

```
CALL RANDOM (ranval)
```

`ranval`

(Output) REAL(4). Pseudorandom number, $0 \leq ranval < 1$, from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RNDSTIMESEED (defined in IFQWIN.F90) to SEED before the first call to RANDOM.
The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "SEED", "DRAND, DRANDM", "IRAND, IRANDM", "RAND, RANDOM", the RANDOM_NUMBER intrinsic subroutine in the Language Reference

**Example**

USE IFPORT
REAL(4) ran
CALL SEED(1995)
CALL RANDOM(ran)

See also the second example in "RAND, RANDOM", which shows how to use both the RANDOM function and the RANDOM subroutine.

---

**RANF**

**Portability Function:** Generates a random number between 0.0 and RAND_MAX.

**Module:** USE IFPORT

**Syntax**

result = RANF ( )

**Results:**

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and RAND_MAX as defined in the C library, normally 0x7FFF 215–1.

The initial seed is set by the following:

CALL SRAND(ISEED)

where ISEED is type INTEGER(4).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
RANGET

Portability Subroutine: Returns the current seed.
Module: USE IFPORT
Syntax
   CALL RANGET (seed)
seed
(Output) INTEGER(4). The current seed value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “DRANSET”, “RANSET”

RANSET

Portability Subroutine: Sets the seed for the random number generator.
Module: USE IFPORT
Syntax
   CALL RANSET (seed)
seed
(Input) REAL(4). The reset value for the seed.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “RANGET”

RECTANGLE, RECTANGLE_W

Graphics Functions: Draw a rectangle using the current graphics color, logical write mode, and line style. These functions are only available on Windows* systems.
Module: USE IFQWIN
Syntax
   result = RECTANGLE (control, x1, y1, x2, y2)
   result = RECTANGLE_W (control, wx1, wy1, wx2, wy2)
control (Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in IFQWIN.F90):
- $GFILLINTERIOR – Draws a solid figure using the current color and fill mask.
- $GBORDER – Draws the border of a rectangle using the current color and line style.

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of rectangle.

x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of rectangle.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of rectangle.

Results:
The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0.
The RECTANGLE function uses the viewport-coordinate system. The viewport coordinates (x1, y1) and (x2, y2) are the diagonally opposed corners of the rectangle.
The RECTANGLE_W function uses the window-coordinate system. The window coordinates (wx1, wy1) and (wx2, wy2) are the diagonally opposed corners of the rectangle.

SETCOLORRGB sets the current graphics color. SETFILLMASK sets the current fill mask. By default, filled graphic shapes are filled solid with the current color.
If you fill the rectangle using FLOODFILLRGB, the rectangle must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE. The RECTANGLE routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the Rectangle routine by including the IFWIN module, you need to specify the routine name as MSFWINSRectangle. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB
See Also: "SETFILLMASK", "GRSTATUS", "LINETO, LINETO_W", "POLYGON, POLYGON_W", "FLOODFILLRGB, FLOODFILLRGB_W", "SETLINESTYLE", "SETCOLOR", "SETWRITEMODE"

Example

This program draws the rectangle shown below.

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
dummy = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
END

REGISTERMOUSEEVENT

QuickWin Function: Registers the application-supplied callback routine to be called when a specified mouse event occurs in a specified window. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = REGISTERMOUSEEVENT (unit, mouseevents, callbackroutine)

unit
(Input) INTEGER(4). Unit number of the window whose callback routine on mouse events is to be registered.

mouseevents
(Input) INTEGER(4). One or more mouse events to be handled by the callback routine to be registered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:
• MOUSE$LBUTTONDOWN – Left mouse button down
• MOUSE$LBUTTONUP – Left mouse button up
• MOUSE$LBUTTONDBLCLK – Left mouse button double-click
• MOUSE$RBUTTONDOWN – Right mouse button down
• MOUSE$RBUTTONUP – Right mouse button up
• MOUSE$RBUTTONDBLCLK – Right mouse button double-click
• MOUSE$MOVE – Mouse moved

callbackroutine
(Input) Routine to be called on the specified mouse event in the specified window. It must be declared EXTERNAL. For a prototype mouse callback routine, see "Using QuickWin" in Building Applications.

Results:
The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:
• MOUSE$BADUNIT – The unit specified is not open, or is not associated with a QuickWin window.
• MOUSE$BADEVENT – The event specified is not supported.
For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system’s CONTROL PANEL/MOUSE.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "UNREGISTERMOUSEEVENT", "WAITONMOUSEEVENT", "Using QuickWin" in Building Applications

Example
The following example registers the routine CALCULATE, to be called when the user double-clicks the left mouse button while the mouse cursor is in the child window opened as unit 4:
USE IFQWIN
INTEGER(4) result
OPEN (4, FILE= 'USER')
...
result = REGISTERMOUSEEVENT (4, MOUSE$LBUTTONDBLCLK, CALCULATE)
**REMAPALLPALETTERGB**

**Graphics Function:** Remaps a set of Red-Green-Blue (RGB) color values to indexes recognized by the video hardware. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = REMAPALLPALETTERGB (colors)
```

**colors**

(Input) INTEGER(4). Ordered array of RGB color values to be mapped in order to indexes. Must hold 0–255 elements.

**Results:**

The result type is INTEGER(4). The result is 0 if successful; otherwise, –1.

The REMAPALLPALETTERGB function remaps all of the available color indexes simultaneously (up to 236; 20 indexes are reserved by the operating system). The `colors` argument points to an array of RGB color values. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in `IFQWIN.F90`.

<table>
<thead>
<tr>
<th>Index</th>
<th>Color</th>
<th>Index</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$BLACK</td>
<td>8</td>
<td>$GRAY</td>
</tr>
<tr>
<td>1</td>
<td>$BLUE</td>
<td>9</td>
<td>$LIGHTBLUE</td>
</tr>
<tr>
<td>2</td>
<td>$GREEN</td>
<td>10</td>
<td>$LIGHTGREEN</td>
</tr>
<tr>
<td>3</td>
<td>$CYAN</td>
<td>11</td>
<td>$LIGHTCYAN</td>
</tr>
<tr>
<td>4</td>
<td>$RED</td>
<td>12</td>
<td>$LIGHTRED</td>
</tr>
<tr>
<td>5</td>
<td>$MAGENTA</td>
<td>13</td>
<td>$LIGHTMAGENTA</td>
</tr>
<tr>
<td>6</td>
<td>$BROWN</td>
<td>14</td>
<td>$YELLOW</td>
</tr>
<tr>
<td>7</td>
<td>$WHITE</td>
<td>15</td>
<td>$BRIGHTWHITE</td>
</tr>
</tbody>
</table>

The number of colors mapped can be fewer than 236 if the number of colors supported by the current video mode is fewer, but at most 236 colors can be mapped by REMAPALLPALETTERGB. Most Windows graphics drivers support a palette of 256K colors or more, of which only a few can be mapped into the 236 palette indexes at a time. To access and use all colors on the system, bypass the palette and use direct RGB color functions such as such as SETCOLORRGB and SETPIXELSRGB.
Any RGB colors can be mapped into the 236 palette indexes. Thus, you could specify a palette with 236 shades of red. For further details on using different color procedures see "Adding Color" in Building Applications.

In each RGB color value, each of the three colors, red, green and blue, is represented by an eight-bit value (2 hex digits). In the values you specify with REMAPALLPALETTERGB or REMAPPALETTERGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'008080' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "REMAPPALETTERGB", "SETBKCOLORRGB", "SETCOLORRGB", "SETBKCOLOR", "SETCOLOR"

**Example**

```
! Build as QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) colors(3)
INTEGER(2) status
colors(1) = Z'00FFFF' ! yellow
colors(2) = Z'FFFFFF' ! bright white
colors(3) = 0       ! black
status = REMAPALLPALETTERGB(colors)
status = REMAPPALETTERGB(INT2(47), Z'45A315')
END
```

**REMAPPALETTERGB**

**Graphics Function:** Remaps one color index to an RGB color value. This function is only available on Windows* systems.

**Module:** USE IFQWIN

---

2-373
Syntax

\[ \text{result} = \text{REMAPPALETTERGB} \left( \text{index}, \text{color} \right) \]

\text{index}

(Input) INTEGER(4). Color index to be reassigned an RGB color.

\text{color}

(Input) INTEGER(4). RGB color value to assign to a color index.

Results:

The result type is INTEGER(4). The result value is the previous color assigned to the index.

The REMAPPALETTERGB function remaps one of the available color indexes (up to 236; 20 indexes are reserved by the operating system). The \text{color} argument is the RGB color value to assign. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in \texttt{IFQWIN.F90}.

<table>
<thead>
<tr>
<th>Index</th>
<th>Color</th>

Example
See the example in “REMAPALLPALETTERGB”.

RENAME

**Portability Function:** Renames a file.

**Module:** USE IFPORT

**Syntax**

```plaintext
result = RENAME (from, to)
```

**from**
(Input) Character*(*). Path of an existing file.

**to**
(Input) Character*(*). The new path for the file (see Caution note below).

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

- **EACCES** – The file or directory specified by `to` could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
- **ENOENT** – The file or path specified by `from` could not be found.
2 Intel Fortran Libraries Reference

- EXDEV – Attempt to move a file to a different device.

CAUTION. This routine can cause data to be lost. If the file specified in "to" already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.
The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “RENAMEFILEQQ”

RENAMEFILEQQ

Portability Function: Renames a file.
Module: USE IFPORT

Syntax

\[ \text{result} = \text{RENAMEFILEQQ} \left( \text{oldname}, \text{newname} \right) \]

oldname
(Input) Character*(*). Current name of the file to be renamed.

newname
(Input) Character*(*). New name of the file to be renamed.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the newname parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERRSACCES – Permission denied. The file’s permission setting does not allow the specified access.
- ERRSEXIST – The file already exists.
- ERRSNOENT – File or path specified by oldname not found.
- ERRSXDEV – Attempt to move a file to a different device.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “FINDFILEQQ”, “RENAME”, “GETLASTERRORQQ”

Example
USE IFPORT
USE IFCORE
INTEGER(4) len
CHARACTER(80) oldname, newname
LOGICAL(4) result

WRITE(*,'(A, \)') ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,'(A, \)') ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END

RGBTOINTEGER

QuickWin Function: Converts three integers specifying red, green, and blue color intensities into a four-byte RGB integer for use with RGB functions and subroutines. This function is only available on Windows® systems.

Module: USE IFQWIN

Syntax
result = RGBTOINTEGER (red, green, blue)

red
(Input) INTEGER(4). Intensity of the red component of the RGB color value. Only the lower 8 bits of red are used.
green
(Input) INTEGER(4). Intensity of the green component of the RGB color value. Only the lower 8 bits of green are used.
blue
(Input) INTEGER(4). Intensity of the blue component of the RGB color value. Only the lower 8 bits of blue are used.
Results:
The result type is INTEGER(4). The result is the combined RGB color value.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value returned with RGBTOINTEGER, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O O O</td>
<td>B B B B B B</td>
<td>G G G G G G G G</td>
<td>R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

Compatibility
QUICKWIN GRAPHICS LIB

Example
! Build as a QuickWin App.
USE IFQWIN
INTEGER r, g, b, rgb, result
INTEGER(2) status
r = Z’F0’
g = Z’F0’
b = 0
rgb = RGBTOINTEGER(r, g, b)
result = SETCOLORRGB(rgb)
status = ELLIPSE($GFILLINTERIOR, INT2(40), INT2(55), &
INT2(90), INT2(85))
END

RINDEX

Portability Function: Locates the index of the last occurrence of a substring within a string.
Module: USE IFPORT
Syntax
result = RINDEX (string, substr)

string
(Input) Character*(*)
Original string to search.

substr
(Input) Character*(*)
String to search for.

Results:
The result type is INTEGER(4).
The result is the starting position of the final occurrence of substr in string.
The result is zero if substr does not occur in string.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWSDLL LIB

See Also:
the INDEX intrinsic function in the Language Reference

Example
USE IFPORT
classeral*80 mainstring
classeral*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring,shortstr)
! where is 19

RTC

Portability Function:
Returns the number of seconds elapsed since a specific Greenwich mean time.

Module:
USE IFPORT

Syntax
result = RTC ()

Results:
The result type is REAL(8).
The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWSDLL LIB
See Also: “TIMEF”, the DATE_AND_TIME intrinsic procedure in the Language Reference

Example
USE IFPORT
real(8) s, s1, time_spent
INTEGER(4) i, j
s = RTC()
call sleep(4)
s1 = RTC() t
ime_spent = s1 - s
PRINT *, 'It took ',time_spent, 'seconds to run.'

RUNQQ

Portability Function: Executes another program and waits for it to complete.

Module: USE IFPORT

Syntax
result = RUNQQ (filename, commandline)

filename
(Input) Character*(*). File name of a program to be executed.

commandline
(Input) Character*(*). Command-line arguments passed to the program to be executed.

Results:
The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the
exit code of that program is returned to the program that launched it. If the program fails, –1 is
returned.

The RUNQQ function executes a new process for the operating system using the same path,
environment, and resources as the process that launched it. The launching process is suspended
until execution of the launched process is complete.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SYSTEM”, “NLSEnumCodepages”

Example
USE IFPORT
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
SAVEIMAGE, SAVEIMAGE_W

Graphics Functions: Save an image from a specified portion of the screen into a Windows bitmap file. These functions are only available on Windows* systems.

Module: USE IFQWIN

Syntax
result = SAVEIMAGE (filename, ulxcoord, ulycoord, lrxcoord, lrycoord)
result = SAVEIMAGE_W (filename, ulwxcoord, ulwycoord, lrwxcoord, lrwycoord)

filename (Input) Character*(*). Path of the bitmap file.
ulxcoord, ulycoord (Input) INTEGER(4). Viewport coordinates for upper-left corner of the screen image to be captured.
lrxcoord, lrycoord (Input) INTEGER(4). Viewport coordinates for lower-right corner of the screen image to be captured.
ulwxcoord, ulwycoord (Input) REAL(8). Window coordinates for upper-left corner of the screen image to be captured.
lrwxcoord, lrwycoord (Input) REAL(8). Window coordinates for lower-right corner of the screen image to be captured.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.
The SAVEIMAGE function captures the screen image within a rectangle defined by the upper-left and lower-right screen coordinates and stores the image as a Windows bitmap file specified by filename. The image is stored with a palette containing the colors displayed on the screen.
SAVEIMAGE defines the bounding rectangle in viewport coordinates. SAVEIMAGE_W defines the bounding rectangle in window coordinates.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETIMAGE, GETIMAGE_W”, “IMAGESIZE, IMAGESIZE_W”, “LOADIMAGE, LOADIMAGE_W”, “PUTIMAGE, PUTIMAGE_W”
SCANNENV

**Portability Subroutine:** Scans the environment for the value of an environment variable.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL SCANENV (envname, envtext, envvalue)
```

- **envname**
  - (Input) Character*(*). Contains the name of an environment variable you need to find the value for.

- **envtext**
  - (Output) Character*(*). Set to the full text of the environment variable if found, or to ’ ’ if nothing is found.

- **envvalue**
  - (Output) Character*(*). Set to the value associated with the environment variable if found or to ’ ’ if nothing is found.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

SCROLLTEXTWINDOW

**Graphics Subroutine:** Scrolls the contents of a text window. This subroutine is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
CALL SCROLLTEXTWINDOW (rows)
```

- **rows**
  - (Input) INTEGER(2). Number of rows to scroll.

The SCROLLTEXTWINDOW subroutine scrolls the text in a text window (previously defined by SETTEXTWINDOW). The default text window is the entire window.

The **rows** argument specifies the number of lines to scroll. A positive value for **rows** scrolls the window up (the usual direction); a negative value scrolls the window down. Specifying a number larger than the height of the current text window is equivalent to calling CLEARSCREEN (SGWINDOW). A value of 0 for **rows** has no effect.
Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “CLEARSCREEN”, “GETTEXTPOSITION”, “GETTEXTWINDOW”, “GRSTATUS”, “OUTTEXT”, “SETTEXTPOSITION”, “SETTEXTWINDOW”, “WRAPON”

Example
!
Build as QuickWin or Standard Graphics app.
USE IFQWIN
INTEGER(2) row, istat
CHARACTER(18) string
TYPE (rccoord) oldpos

CALL SETTEXTWINDOW (INT2(1), INT2(0), &
   INT2(25), INT2(80))
CALL CLEARSCREEN ( $GCLEARSCREEN )
CALL SETTEXTPOSITION (INT2(1), INT2(1), oldpos)
DO row = 1, 6
   string = 'Hello, World # '
   CALL SETTEXTPOSITION( row, INT2(1), oldpos )
   WRITE(string(15:16), '(I2)') row
   CALL OUTTEXT(string)
END DO
istat  = displaycursor($GCURSORON)
WRITE(*,'(1x,A)') 'Hit ENTER'
READ (*,*) ! wait for ENTER
! Scroll window down 4 lines
CALL SCROLLTEXTWINDOW(INT2( -4) )
CALL SETTEXTPOSITION (INT2(10), INT2(18), oldpos)
WRITE(*,'(2X,A)') "Hit ENTER"
READ( *,*) ! wait for ENTER
! Scroll window up 5 lines
CALL SCROLLTEXTWINDOW( INT2(5 ))
END

SCWRQQ

Portability Subroutine: Returns the floating-point processor control word.
Module: USE IFPORT
Syntax
CALL SCWRQQ (control)

control
(Output) INTEGER(2). Floating-point processor control word.
SCRWQQ performs the same function as the run-time subroutine GETCONTROLFPPQQ, and is
provided for compatibility.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “GETCONTROLFPOQ”, “LCWRQQ”

Example
See the example in “LCWRQQ”.

SECNDS

Portability Function: Returns the number of seconds that have elapsed since midnight, less the
value of its argument.
Module: USE IFPORT
Syntax:
result = SECNDS (r)

r
(Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.
Results:
The result type is REAL(4). The result value is the number of seconds that have elapsed since
midnight, minus r, with a precision of a hundredth of a second (0.01).
To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the
elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

NOTE. SECNDS is an intrinsic procedure unless you specify USE IFPORT.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB
See Also: “RTC”, “TIME”, the DATE_AND_TIME and SYSTEM_CLOCK subroutines and the
SECNDS function in the Language Reference
Example
USE IFPORT
REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
   J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ', s, ' seconds to run.'

SEED

Portability Subroutine: Changes the starting point of the pseudorandom number generator.
Module: USE IFPORT
Syntax
   CALL SEED (iseed)
iseed
(Input) INTEGER(4). Starting point for RANDOM.
SEED uses iseed to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.
If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RNDSTIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.
This routine is not thread-safe.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “RANDOM”, the RANDOM_SEED and RANDOM_NUMBER intrinsic subroutines in the Language Reference
Example
USE IFPORT
REAL myrand
CALL SEED(7531)
CALL RANDOM(myrand)
2 Intel Fortran Libraries Reference

**SETACTIVEQQ**

**QuickWin Function:** Makes a child window active, but does not give it focus. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = SETACTIVEQQ (unit)
```

*unit*

(Input) INTEGER(4). Unit number of the child window to be made active.

**Results:**

The result type is INTEGER(4). The result is 1 if successful; otherwise, 0.

When a window is made active, it receives graphics output (from ARC, LINETO and OUTGTEXT, for example) but is not brought to the foreground and does not have the focus. If a window needs to be brought to the foreground, it must be given the focus. A window is given focus with FOCUSQQ, by clicking it with the mouse, or by performing I/O other than graphics on it, unless the window was opened with IOFOCUS='FALSE.'. By default, IOFOCUS='TRUE.', except for child windows opened as unit '*'.

The window that has the focus is always on top, and all other windows have their title bars grayed out. A window can have the focus and yet not be active and not have graphics output directed to it. Graphical output is independent of focus.

If IOFOCUS='TRUE.', the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**Compatibility**

QUICKWIN GRAPHICS LIB

**See Also:** "GETACTIVEQQ", "FOCUSQQ", "INOFOCUSQQ", "Using QuickWin" in **Building Applications**

**SETBKCOLOR**

**Graphics Function:** Sets the current background color index for both text and graphics. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = SETBKCOLOR (color)
```

*color*

(Input) INTEGER. The new background color index.
**color**

(Input) INTEGER(4). Color index to set the background color to.

**Results:**

The result type is INTEGER(4). The result is the previous background color index.

SETBKCOLOR changes the background color index for both text and graphics. The color index of text over the background color is set with SETTEXTCOLOR. The color index of graphics over the background color (used by drawing functions such as FLOODFILL and ELLIPSE) is set with SETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Changing the background color index does not change the screen immediately. The change becomes effective when CLEARSCREEN is executed or when doing text input or output, such as with READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background color index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.

---

**NOTE.** The SETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the SetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWINSSetBkColor. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines” in Building Applications.

---

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** “SETBKCOLORRGB”, “GETBKCOLOR”, “REMAPALLPALETTERGB”, “REMAPPALETTERGB”, “SETCOLOR”, “SETTEXTCOLOR”

**Example**

USE IFQWIN

INTEGER(4) i

i = SETBKCOLOR(14)
Graphics Function: Sets the current background color to the given Red-Green-Blue (RGB) value. This function is only available on Windows® systems.

Module: USE IFQWIN

Syntax

result = SETBKCOLORRGB (color)

color

(Input) INTEGER(4). RGB color value to set the background color to. Range and result depend on the system’s display adapter.

Results:
The result type is INTEGER(4). The result is the previous background RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>OOOOOOOO</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFF00' full-intensity for all three, resulting in bright white.

The default background color is value 0, which is black. Changing the background color value does not change the screen immediately, but becomes effective when CLEARSCREEN is executed or when doing text input or output such as READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors
available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** "GETBKCOLORRGB" "SETCOLORRGB" "SETTEXTCOLORRGB" "SETPIXELRGB, SETPIXELRGB_W" "SETPIXELSRGB" "SETBKCOLOR"

**Example**

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETBKCOLORRGB(Z'FF0000') !blue
oldcolor = SETCOLORRGB(Z'FF') ! red
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

**SETCLIPRGN**

**Graphics Subroutine:** Limits graphics output to part of the screen. This subroutine is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

CALL SETCLIPRGN (x1, y1, x2, y2)

x1, y1
(Input) INTEGER(2). Physical coordinates for upper-left corner of clipping region.

x2, y2
(Input) INTEGER(2). Physical coordinates for lower-right corner of clipping region.
The SETCLIPRGN function limits the display of subsequent graphics output and font text output to that which fits within a designated area of the screen (the "clipping region"). The physical coordinates \((x_1, y_1)\) and \((x_2, y_2)\) are the upper-left and lower-right corners of the rectangle that defines the clipping region. The SETCLIPRGN function does not change the viewport-coordinate system; it merely masks graphics output to the screen.

SETCLIPRGN affects graphics and font text output only, such as OUTGTEXT. To mask the screen for text output using OUTTEXT, use SETTEXTWINDOW.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** "GETPHYSCOORD", "GRSTATUS", "SETTEXTWINDOW", "SETVIEWORG", "SETVIEWPORT", "SETWINDOW"

**Example**

This program draws an ellipse lying partly within a clipping region, as shown below.

```fortran
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2
INTEGER(4) oldcolor
x1 = 10;  y1 = 50
x2 = 170; y2 = 150
! Draw full ellipse in white
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
oldcolor = SETCOLORRGB(Z'FF0000') ! blue
WRITE(*,*) "Hit enter"
READ(*,*)
CALL CLEARSCREEN($GCLEARSCREEN) ! clear screen
CALL SETCLIPRGN( INT2(0), INT2(0), &
                  INT2(150), INT2(125))  ! only part of ellipse inside clip region drawn now
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

The following figure shows the output of this program.
SETCOLOR

**Graphics Function:** Sets the current graphics color index. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**
```
result = SETCOLOR (color)
```

**color**
(Input) INTEGER(2). Color index to set the current graphics color to.

**Results:**
The result type is INTEGER(2). The result is the previous color index if successful; otherwise, –1.

The SETCOLOR function sets the current graphics color index, which is used by graphics functions such as ELLIPSE. The background color index is set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** “SETCOLORRGB”, “GETCOLOR”, “REMAPPALETTERGB”, “SETBKCOLOR”, “SETTEXTCOLOR”, “SETPIXEL, SETPIXEL_W”, “SETPIXELS”
Example

USE IFQWIN
INTEGER(2) color, oldcolor
LOGICAL status
TYPE (windowconfig) wc

status = GETWINDOWCONFIG(wc)
color = wc%numcolors - 1
oldcolor = SETCOLOR(color)
END

SETCOLORRGB

Graphics Function: Sets the current graphics color to the specified Red-Green-Blue (RGB) value. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = SETCOLORRGB (color)

color

(Input) INTEGER(4). RGB color value to set the current graphics color to. Range and result depend on the system’s display adapter.

Results:

The result type is INTEGER(4). The result is the previous RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFF000' full-intensity for all three, resulting in bright white.
SETCOLORRGB sets the RGB color value of graphics over the background color, used by the following graphics functions: ARC, ELLIPSE, FLOODFILL, LINETO, OUTGTEXT, PIE, POLYGON, RECTANGLE, and SETPIXEL. SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETTEXTCOLORRGB sets the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT).

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) oldcolor
TYPE (xycoord) xy
numfonts = INITIALIZEFONTS( )
oldcolor = SETCOLORRGB(Z'0000FF')   ! red
oldcolor = SETBKCOLORRGB(Z'00FF00') ! green
CALL MOVETO(INT2(200), INT2(100), xy)
CALL OUTGTEXT("hello, world")
END

SETCONTROLFPQQ

Portability Subroutine: Sets the value of the floating-point processor control word.

Module: USE IFPORT
Syntax

CALL SETCONTROLFPQQ (controlword)

call

(Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math coprocessor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z'1000'</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z'1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z'0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z'0300'</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z'0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z'0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z'0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z'0C00'</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z'0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z'0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z'0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z'0000'</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z'003F'</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>Z'0001'</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>FPCW$DENORMAL</td>
<td>Z'0002'</td>
<td>Allow denormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZERODIVIDE</td>
<td>Z'0004'</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>Z'0008'</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>Z'0010'</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z'0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

The defaults for the floating-point control word are 53-bit precision, round to nearest, and the denormal, underflow and inexact precision exceptions disabled. An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.
Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.

For a full discussion of the floating-point control word, exceptions, and error handling, see “The Floating-Point Environment” in Building Applications.

NOTE. The Intel® Visual Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Visual Fortran with another compiler.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “GETCONTROLFPQQ”, “GETSTATUSFPQQ”, “LCWRQQ”, “SCWRQQ”, “CLEARSTATUSFPQQ”

Example
USE IFPORT
INTEGER(2) status, control, controlo
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
!     Save old control word
controlo = control
!     Clear all flags
control = control .AND. Z'0000'
!     Set new control to round up
control = control .OR. FPCW$UP
CALL SETCONTROLFPQQ(control)
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
SETDAT

**Portability Function:** Sets the system date. This function is only available on Windows* and Linux* systems.

**Module:** USE IFPORT

**Syntax**

```
result = SETDAT (iyr, imon, iday)
```

- **iyr**
  (Input) INTEGER(2) or INTEGER(4). Year (xxxx AD).
- **imon**
  (Input) INTEGER(2) or INTEGER(4). Month (1-12).
- **iday**
  (Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

**Results:**
The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.

Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.

Refer to your operating system documentation for the range of permitted dates.

---

NOTE. On Linux systems, you must have root privileges to execute this function.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "GETDAT", "GETTIM", "SETTIM"

**Example**

```
USE IFPORT
LOGICAL(4) success
success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))
```
SETENVQQ

Portability Function: Sets the value of an existing environment variable, or adds and sets a new environment variable.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{SETENVQQ} \left( \text{varname} = \text{value} \right)
\]

\(\text{varname} = \text{value}\)

(Input) Character*(*). String containing both the name and the value of the variable to be added or modified. Must be in the form: \(\text{varname} = \text{value}\), where \(\text{varname}\) is the name of an environment variable and \(\text{value}\) is the value being assigned to it.

Results:
The result is of type \text{LOGICAL}(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate \(\text{value}\) so that trailing blanks are preserved. For example, the string \(\text{PATH}=\) sets \(\text{value}\) to \(\text{}\).

You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, \(\text{LIB=}\) removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.
SETENVQQ and GETENVQQ will not work properly with the Windows* APIs SetEnvironmentVariable and GetEnvironmentVariable.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL LIB

See Also: “GETENVQQ”, “RUNQQ”

**Example**

```fortran
USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
   SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END
```

**SETERRORMODEQQ**

**Portability Subroutine**: Sets the prompt mode for critical errors that by default generate system prompts.

**Module**: USE IFPORT

**Syntax**

```fortran
CALL SETERRORMODEQQ (pmode)
```

**pmode**

(Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (pmode = .TRUE.). You can also enable system error prompts by calling SETERRORMODEQQ with pmode set to ERR$HARDPROMPT (defined in IFPORT.F90).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting pmode to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).
SETERRORMODEQQ affects only errors that generate a system prompt. It does not affect other 
I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with 
STATUS='OLD'.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

! PROGRAM 1
  ! DRIVE B door open
  OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
  ! Generates a system prompt error here and waits for the user
  ! to respond to the prompt before continuing
  100   WRITE(*,*) ' Continuing'
END

! PROGRAM 2
  ! DRIVE B door open
  USE IFPORT
  CALL SETERRORMODEQQ(.FALSE.)
  OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
  ! Causes the statement at label 100 to execute
  ! without system prompt
  100   WRITE(*,*) ' Drive B: not available, opening &
          &alternative drive.'
          OPEN (10, FILE = 'C:\NOFILE.DAT')
END

SETEXITQQ

QuickWin Function: Sets a QuickWin application’s exit behavior. This function is only available 
on Windows® systems.

Module: USE IFQWIN

Syntax

result = SETEXITQQ (exitmode)

exitmode
(Input) INTEGER(4). Determines the program exit behavior. The following exit parameters are 
defined in IFQWIN.F90:

• QWINEXITPROMPT – Displays the following message box:
"Program exited with exit status X. Exit Window?"
where X is the exit status from the program.
If Yes is entered, the application closes the window and terminates. If No is entered, the
dialog box disappears and you can manipulate the windows as usual. You must then close the
window manually.

- QWIN$EXITNOPERSIST – Terminates the application without displaying a message box.
- QWIN$EXITPERSIST – Leaves the application open without displaying a message box.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.
The default for both QuickWin and Standard Graphics applications is QWIN$EXITPROMPT.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “GETEXITQQ”, “Using QuickWin” in Building Applications

Example
! Build as QuickWin Ap
USE IFQWIN
INTEGER(4) exmode, result
WRITE(*,'(1X,A,/)') 'Please enter the exit mode 1, 2 & or 3'
READ(*,*) exmode
SELECT CASE (exmode)
   CASE (1)
      result = SETEXITQQ(QWIN$EXITPROMPT)
   CASE (2)
      result = SETEXITQQ(QWIN$EXITNOPERSIST)
   CASE (3)
      result = SETEXITQQ(QWIN$EXITPERSIST)
   CASE DEFAULT
      WRITE(*,*) 'Invalid option - checking for bad return'
      IF(SETEXITQQ( exmode ) .NE. -1) THEN
         WRITE(*,*) 'Error not returned'
      ELSE
         WRITE(*,*) 'Error code returned'
      ENDIF
END SELECT
SETFILEACCESSQQ

**Portability Function:** Sets the file access mode for a specified file.

**Module:** USE IFPORT

**Syntax**

```
result = SETFILEACCESSQQ (filename, access)
```

*filename*

(Input) Character*(*)*. Name of a file to set access for.

*access*

(Input) INTEGER(4). Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such as IOR or OR):

- FILE$ARCHIVE – Marked as having been copied to a backup device.
- FILE$HIDDEN – Hidden. The file does not appear in the directory list that you can request from the command console.
- FILE$NORMAL – No special attributes (default).
- FILE$READONLY – Write-protected. You can read the file, but you cannot make changes to it.
- FILE$SYSTEM – Used by the operating system.

The flags are defined in module IFPORT.F90.

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

To set the access value for a file, add the constants representing the appropriate access.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “GETFILEINFOQQ”

**Example**

```
USE IFPORT
INTEGER(4) permit
LOGICAL(4) result

permit = 0   ! clear permit
permit = IOR(FILE$READONLY, FILE$HIDDEN)
result = SETFILEACCESSQQ ('formula.f90', permit)
```
SETFILETIMEQQ

Portability Function: Sets the modification time for a specified file.

Module: USE IFPORT

Syntax

result = SETFILETIMEQQ(filename, timedate)

filename

timedate
(Input) INTEGER(4) . Time and date information, as packed by PACKTIMEQQ.

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of
different versions of the file. The process that calls SETFILETIMEQQ must have write access to
the file; otherwise, the time cannot be changed. If you set timedate to FILE$CURTIME (defined in
IFPORT.F90), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the
following:
• ERR$ACCES – Permission denied. The file’s (or directory’s) permission setting does not
  allow the specified access.
• ERR$INVAL – Invalid argument; the timedate argument is invalid.
• ERR$MFFILE – Too many open files (the file must be opened to change its modification
time).
• ERR$NOENT – File or path not found.
• ERR$NOMEM – Not enough memory is available to execute the command; or the available
  memory has been corrupted; or an invalid block exists, indicating that the process making the
call was not allocated properly.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PACKTIMEQQ”, “UNPACKTIMEQQ”, “GETLASTERRORQQ”

Example
USE IFPORT
INTEGER(2) day, month, year
**SETFILLMASK**

**Graphics Subroutine:** Sets the current fill mask to a new pattern. This subroutine is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```
CALL SETFILLMASK (mask)
```

*mask*

(Input) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in *mask*, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of *mask* becomes the top 8 bits of the pattern, and the eighth element (byte) of *mask* becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of zero are set to the current background color. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

To change the current fill mask, determine the array of bytes that corresponds to the desired bit pattern and set the pattern with SETFILLMASK, as in the following example.
Bit pattern | Value In mask
--- | ---
● ○ ○ ● ○ ○ ● ● | mask(1) = ‘Z’93’
● ● ○ ○ ● ○ ● ● | mask(2) = ‘Z’C9’
○ ● ● ○ ○ ● ○ ● | mask(3) = ‘Z’64’
● ● ● ○ ○ ● ○ ● | mask(4) = ‘Z’B2’
○ ● ● ● ○ ● ○ ● | mask(5) = ‘Z’59’
○ ○ ● ● ● ○ ● ● | mask(6) = ‘Z’2C’
● ○ ● ● ● ● ● ● | mask(7) = ‘Z’96’
● ● ● ● ● ● ● ● | mask(8) = ‘Z’4B’

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB
See Also: “ELLIPSE, ELLIPSE_W”, “FLOODFILLRGB, FLOODFILLRGB_W”, “GETFILLMASK”, “PIE, PIE_W”, “POLYGON, POLYGON_W”, “RECTANGLE, RECTANGLE_W”

Example
This program draws six rectangles, each with a different fill mask, as shown below.
USE IFQWIN
INTEGER(1), TARGET :: style1(8) &
INTEGER(1), TARGET :: style2(8) &
INTEGER(1), TARGET :: style3(8) &
INTEGER(1), TARGET :: style4(8) &
INTEGER(1), TARGET :: style5(8) &
INTEGER(1), TARGET :: style6(8) &
INTEGER(1) oldstyle(8) ! Placeholder for old style
INTEGER loop
INTEGER(1), POINTER :: ptr(:)

CALL GETFILLMASK( oldstyle )  ! Make 6 rectangles, each with a different fill
DO loop = 1, 6
  SELECT CASE (loop)
  CASE (1)
    ptr => style1
  CASE (2)
    ptr => style2
  CASE (3)
    ptr => style3
  CASE (4)
    ptr => style4
  CASE (5)
    ptr => style5
  CASE (6)
    ptr => style6
  END SELECT
  CALL SETFILLMASK( ptr)
  status = RECTANGLE($GFILLINTERIOR,INT2(loop*40+5), &
   INT2(90),INT2((loop+1)*40), INT2(110))
END DO

CALL SETFILLMASK( oldstyle )  ! Restore old style
READ (*)                    ! Wait for ENTER to be
!   pressed
END

The following shows the output of this program.

Typical fill masks for rectangle
SETFONT

**Graphics Function:** Finds a single font that matches a specified set of characteristics and makes it the current font used by the OUTGTEXT function. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = SETFONT (options)
```

*options*

(Input) Character*(*). String describing font characteristics (see below for details).

**Results:**

The result type is INTEGER(2). The result is the index number (x as used in the nx option) of the font if successful; otherwise, -1.

The SETFONT function searches the list of available fonts for a font matching the characteristics specified in options. If a font matching the characteristics is found, it becomes the current font. The current font is used in all subsequent calls to the OUTGTEXT function. There can be only one current font.

The options argument consists of letter codes, as follows, that describe the desired font. The options parameter is neither case sensitive nor position sensitive.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>'fontname'</td>
</tr>
<tr>
<td>h</td>
<td>y</td>
</tr>
<tr>
<td>w</td>
<td>x</td>
</tr>
<tr>
<td>f</td>
<td></td>
</tr>
<tr>
<td>p</td>
<td></td>
</tr>
<tr>
<td>v</td>
<td></td>
</tr>
<tr>
<td>r</td>
<td></td>
</tr>
<tr>
<td>e</td>
<td></td>
</tr>
<tr>
<td>u</td>
<td></td>
</tr>
</tbody>
</table>
You can specify as many options as you want, except with \texttt{n\_x}, which should be used alone. If you specify options that are mutually exclusive (such as the pairs \texttt{f/p} or \texttt{r/v}), the \texttt{SETFONT} function ignores them. There is no error detection for incompatible parameters used with \texttt{n\_x}.

If the \texttt{b} option is specified and at least one font is initialized, \texttt{SETFONT} sets a font and returns 0 to indicate success.

In selecting a font, the \texttt{SETFONT} routine uses the following criteria, rated from highest precedence to lowest:

1. Pixel height
2. Typeface
3. Pixel width
4. Fixed or proportional font

You can also specify a pixel width and height for fonts. If you choose a nonexistent value for either and specify the \texttt{b} option, \texttt{SETFONT} chooses the closest match.

A smaller font size has precedence over a larger size. If you request Arial 12 with best fit, and only Arial 10 and Arial 14 are available, \texttt{SETFONT} selects Arial 10.

If you choose a nonexistent value for pixel height and width, the \texttt{SETFONT} function applies a magnification factor to a vector-mapped font to obtain a suitable font size. This automatic magnification does not apply if you specify the \texttt{x} option (raster-mapped font), or if you request a specific typeface and do not specify the \texttt{b} option (best-fit).

If you specify the \texttt{n\_x} parameter, \texttt{SETFONT} ignores any other specified options and supplies only the font number corresponding to \texttt{x}.

If a height is given, but not a width, \texttt{SETFONT} computes the a width to preserve the correct font proportions.

If a width is given, but not a height, \texttt{SETFONT} uses a default height, which may vary from font type to font type. This may lead to characters that appear distorted, particularly when a very wide width is specified. This behavior is the same as that of the Windows* API \texttt{CreateFontIndirect}.

The second example below shows how to calculate the correct height for a given width.

The font functions affect only \texttt{OUTGTEXT} and the current graphics position; no other Fortran Graphics Library output functions are affected by font usage.
For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** “GETFONTINFO”, “GETGTEXTEXTENT”, “GRSTATUS”, “OUTGTEXT”, “INITIALIZEFONTS”, “SETGTEXTROTATION”

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
! Set typeface to Arial, character height to 18,
! character width to 10, and italic
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Demo text')
END
```

Another example follows:

```fortran
! The following program shows you how to compute
! an appropriate font height for a given font width
!
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
TYPE (rccoord) rcc
TYPE (FONTINFO) info
CHARACTER*11 str, str1
CHARACTER*22 str2

REAL rh

integer h, inw
str = "t'Arial'bih"
str1= " "
numfonts = INITIALIZEFONTS ( )
! Default both height and width. This seems to work
```
! properly. From this setting get the ratio between
! height and width.
fontnum = SETFONT("t'Arial'")
intreturn = GETFONTINFO(info)

rh = real(info%pixheight)/real(info%avgwidth)

! Now calculate the height for a width of 40
write(*,*) 'Input desired width:'
read(*,*) inw
h = int(inw*rh)
write(str1,'(I3.3)') h
str2 = str//str1
print *,str2
print *,str2

fontnum = SETFONT(str2)
CALL MOVETO(INT2(10), INT2(50), pos)
CALL OUTGTEXT('ABCDEFGabcdefg12345!@#$%')
CALL MOVETO(INT2(10), INT2(50+10+h), pos)
CALL OUTGTEXT('123456789012345678901234')
intreturn = GETFONTINFO(info)
call settextposition(4,1, rcc)
print *, info%avgwidth, info%pixheight

END

SETGTEXTROTATION

Graphics Subroutine: Sets the orientation angle of the font text output in degrees. The current
orientation is used in calls to OUTGTEXT. This subroutine is only available on Windows*
systems.

Module: USE IFQWIN

Syntax

CALL SETGTEXTROTATION (degree-tenths)

degree-tenths
(Input) INTEGER(4). Angle of orientation, in tenths of degrees, of the font text output.
The orientation of the font text output is set in tenths of degrees. Horizontal is 0°, and angles
increase counterclockwise so that 900 (90°) is straight up, 1800 (180°) is upside down and left,
2700 (270°) is straight down, and so forth. If the user specifies a value greater than 3600 (360°),
the subroutine takes a value equal to:
MODULO (user-specified tenths of degrees, 3600)

Although SETGTEXTROTATION accepts arguments in tenths of degrees, only increments of one
full degree differ visually from each other on the screen.

Bitmap fonts cannot be rotated; TruType fonts should be used instead.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETGTEXTROTATION"

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
INTEGER(4) oldcolor, deg
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Straight text')
deg = -1370
CALL SETGTEXTROTATION(deg)
oldcolor = SETCOLORRGB(Z'008080')
CALL OUTGTEXT('Slanted text')
END

SETLINESTYLE

Graphics Subroutine: Sets the current line style to a new line style. This subroutine is only
available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL SETLINESTYLE (mask)

mask
(Input) INTEGER(2). Desired Quickwin line-style mask. (See the table below.)

The mask is mapped to the style that most closely equivalences the percentage of the bits in the
mask that are set. The style produces lines that cover a certain percentage of the pixels in that line.
SETLINESTYLE sets the style used in drawing a line. You can choose from the following styles:

<table>
<thead>
<tr>
<th>QuickWin Mask</th>
<th>Internal Windows Style</th>
<th>Selection Criteria</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFF</td>
<td>PS_SOLID</td>
<td>16 bits on</td>
<td></td>
</tr>
<tr>
<td>0xEEEE</td>
<td>PS_DASH</td>
<td>11 to 15 bits on</td>
<td></td>
</tr>
<tr>
<td>0xECCE</td>
<td>PS_DASHDOT</td>
<td>10 bits on</td>
<td></td>
</tr>
<tr>
<td>0xECCE</td>
<td>PS_DASHDOTDOT</td>
<td>9 bits on</td>
<td></td>
</tr>
<tr>
<td>0xAAAA</td>
<td>PS_DOT</td>
<td>1 to 8 bits on</td>
<td></td>
</tr>
<tr>
<td>0x0000</td>
<td>PS_NULL</td>
<td>0 bits on</td>
<td></td>
</tr>
</tbody>
</table>

SETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON, and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE, or PIE.

The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** "GETLINESTYLE", "GRSTATUS", "LINETO, LINETO_W", "POLYGON, POLYGON_W", "RECTANGLE, RECTANGLE_W", "SETCOLOR", "SETWRITEMODE"

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2)     status, style
TYPE (xycoord) xy
style = Z'FFFF'
CALL SETLINESTYLE(style)
CALL MOVETO(INT2(50), INT2(50), xy )
status = LINETO(INT2(300), INT2(300))
END
```

**SETMESSAGEQQ**

**QuickWin Subroutine:** Changes QuickWin status messages, state messages, and dialog box messages. This subroutine is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

CALL SETMESSAGEQQ (msg, id)
msg
(Input) Character*(*) Message to be displayed. Must be a regular Fortran string, not a C string. Can include multibyte characters.

id
(Input) INTEGER(4). Identifier of the message to be changed. The following table shows the messages that can be changed and their identifiers:

<table>
<thead>
<tr>
<th>Id</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$MSG_TERM</td>

</tr>
<tr>
<td>QWIN$MSG_TITLETEXT</td>
<td>&quot;Graphic&quot;</td>
</tr>
</tbody>
</table>

QWIN$MSG_FILEOPENDLG and QWIN$MSG_BMPSAVEDLG control the text in file choosing dialog boxes and have the following syntax:

"file description, file designation"
You can change any string produced by QuickWin by calling SETMESSAGEQQ with the appropriate id. This includes status messages displayed at the bottom of a QuickWin application, state messages (such as "Paused"), and dialog box messages. These messages can include multibyte characters. (For more information on multibyte characters, see "Using National Language Support Routines" in Building Applications.) To change menu messages, use MODIFYMENUSTRINGQQ.

**Compatibility**
QUICKWIN GRAPHICS LIB

**See Also:** ["MODIFYMENUSTRINGQQ"]

**Example**

USE IFQWIN
print *, "Hello"
CALL SETMESSAGEQQ('Changed exit text', QWIN$MSG_EXITQ)

---

**SETMOUSECURSOR**

**Quickwin Function:** Sets the shape of the mouse cursor for the window in focus. This function is only available on Windows* systems.

**Modules:** USE IFQWIN, USE IFWIN

**Syntax**

\[
\text{oldcursor} = \text{SETMOUSECURSOR} \left( \text{newcursor} \right)
\]

- \text{newcursor} 
  (Input) INTEGER(4). A Windows HCURSOR value. For many predefined shapes, LoadCursor(0, shape) is a convenient way to get a legitimate value. See the list of predefined shapes in the table shown below in Results.

A value of zero causes the cursor not to be displayed.

**Results:**

The result type is INTEGER(4). This is also an HCURSOR Value. The result is the previous cursor value.

The window in focus at the time SETMOUSECURSOR is called has its cursor changed to the specified value. Once changed, the cursor retains its shape until another call to SETMOUSECURSOR.

In Standard Graphics applications, units 5 and 6 (the default screen input and output units) are always considered to be in focus.
The following predefined values for cursor shapes are available:

<table>
<thead>
<tr>
<th>Predefined Value</th>
<th>Cursor Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDC_APPSTARTING</td>
<td>Standard arrow and small hourglass</td>
</tr>
<tr>
<td>IDC_ARROW</td>
<td>Standard arrow</td>
</tr>
<tr>
<td>IDC_CROSS</td>
<td>Crosshair</td>
</tr>
<tr>
<td>IDC_IBEAM</td>
<td>Text I-beam</td>
</tr>
<tr>
<td>IDC_ICON</td>
<td>Obsolete value</td>
</tr>
<tr>
<td>IDC_NO</td>
<td>Slashed circle</td>
</tr>
<tr>
<td>IDC_SIZE</td>
<td>Obsolete value; use IDC_SIZEALL</td>
</tr>
<tr>
<td>IDC_SIZEALL</td>
<td>Four-pointed arrow</td>
</tr>
<tr>
<td>IDC_SIZENESW</td>
<td>Double-pointed arrow pointing northeast and southwest</td>
</tr>
<tr>
<td>IDC_SIZENS</td>
<td>Double-pointed arrow pointing north and south</td>
</tr>
<tr>
<td>IDC_SIZENWSE</td>
<td>Double-pointed arrow pointing northwest and southeast</td>
</tr>
<tr>
<td>IDC_SIZEWE</td>
<td>Double-pointed arrow pointing west and east</td>
</tr>
<tr>
<td>IDC_UPARROW</td>
<td>Vertical arrow</td>
</tr>
<tr>
<td>IDC_WAIT</td>
<td>Hour glass</td>
</tr>
</tbody>
</table>

A LoadCursor must be done on these values before they can be used by SETMOUSECURSOR.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example:**

```fortran
! Build as Standard Graphics or QuickWin
use IFQWIN

integer*4 cursor, oldcursor
write(6,*) 'The cursor will now be changed to an hour glass shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_WAIT)
oldcursor = SetMouseCursor(cursor)
read(5,*)

write(6,*) 'The cursor will now be changed to a cross-hair shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_CROSS)
oldcursor = SetMouseCursor(cursor)
```
read(5,*)
write(6,*) 'The cursor will now be turned off'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(0)
read(5,*)
write(6,*) 'The cursor will now be turned on'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(oldcursor)
read(5,*)
stop
end

SETPIXEL, SETPIXEL_W

Graphics Functions: Set a pixel at a specified location to the current graphics color index. These functions are only available on Windows* systems.

Module: USE IFQWIN

Syntax
  result = SETPIXEL (x, y)
  result = SETPIXEL_W (wx, wy)

x, y
  (Input) INTEGER(2). Viewport coordinates for target pixel.
wx, wy
  (Input) REAL(8). Window coordinates for target pixel.

Results:
The result type is INTEGER(2). The result is the previous color index of the target pixel if successful; otherwise, –1 (for example, if the pixel lies outside the clipping region).

SETPIXEL sets the specified pixel to the current graphics color index. The current graphics color index is set with SETCOLOR and retrieved with GETCOLOR. The non-RGB color functions (such as SETCOLOR and SETPIXELS) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an
RGB color function, rather than a palette index with a non-RGB color function. SETPIXELRGB and SETPIXELRGB_W give access to the full color capacity of the system by using direct color values rather than indexes to a palette.

NOTE. The SETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft® Platform SDK version of the SetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWINS$SetPixel. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “SETPIXELRGB, SETPIXELRGB_W”, “GETPIXEL, GETPIXEL_W”, “SETPIXELS”, “GETPIXELS”, “GETCOLOR”, “SETCOLOR”

Example
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
status = SETCOLOR(INT2(2))
x = 10
! Draw pixels.
DO y = 50, 389, 3
    status = SETPIXEL( x, y )
x = x + 2
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

SETPIXELRGB, SETPIXELRGB_W

Graphics Functions: Set a pixel at a specified location to the specified Red-Green-Blue (RGB) color value. These functions are only available on Windows® systems.

Module: USE IFQWIN

Syntax
result = SETPIXELRGB (x, y, color)
result = SETPIXELRGB_W (wx, wy, color)
(Input) INTEGER(2). Viewport coordinates for target pixel.

wx, wy
(Input) REAL(8). Window coordinates for target pixel.

color
(Input) INTEGER(4). RGB color value to set the pixel to. Range and result depend on the system’s display adapter.

Results:
The result type is INTEGER(4). The result is the previous RGB color value of the pixel.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETPIXELRGB or SETPIXELRGB_W, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>O O O O O O O</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

If any of the pixels are outside the clipping region, those pixels are ignored.

SETPIXELRGB (and the other RGB color selection functions such as SETPIXELSRGB, SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETPIXELRGB, GETPIXELRGB_W”, “GETPIXELSRGB”, “SETCOLORRGB”, “SETPIXELSRGB”
Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) x, y
INTEGER(4) color
DO i = 10, 30, 10
  SELECT CASE (i)
    CASE (10)
      color = Z'0000FF'
    CASE (20)
      color = Z'00FF00'
    CASE (30)
      color = Z'FF0000'
  END SELECT
  ! Draw pixels.
  DO y = 50, 180, 2
    status = SETPIXELRGB( x, y, color )
    x = x + 2
  END DO
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

SETPIXELS

**Graphics Subroutine:** Sets the color indexes of multiple pixels. This subroutine is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

CALL SETPIXELS (n, x, y, color)

- **n**
  - (Input) INTEGER(4). Number of pixels to set. Sets the number of elements in the other arguments.
- **x, y**
  - (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to set.
color

(Input) INTEGER(2). Array containing color indexes to set the pixels to.

SETPIXELS sets the pixels specified in the arrays \( x \) and \( y \) to the color indexes in \( \text{color} \). These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELS with \( n \) less than 1 are also ignored. SETPIXELS is a much faster way to set multiple pixel color indexes than individual calls to SETPIXEL.

Unlike SETPIXELS, SETPIXELSRGB gives access to the full color capacity of the system by using direct color values rather than indexes to a palette. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETPIXELS", "SETPIXEL, SETPIXEL_W", "SETPIXELSRGB"

Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) color(9)
INTEGER(2) x(9), y(9), i
DO i = 1, 9
   x(i) = 20 * i
   y(i) = 10 * i
   color(i) = INT2(i)
END DO
CALL SETPIXELS(9, x, y, color)
END

SETPIXELSRGB

Graphics Subroutine: Sets multiple pixels to the given Red-Green-Blue (RGB) color. This subroutine is only available on Windows® systems.

Module: USE IFQWIN
Syntax

CALL SETPIXELSRGB (n, x, y, color)

n
(Input) INTEGER(4). Number of pixels to be changed. Determines the number of elements in arrays x and y.

x, y
(Input) INTEGER(2). Parallel arrays containing viewport coordinates of the pixels to set.

color
(Input) INTEGER(4). Array containing the RGB color values to set the pixels to. Range and result depend on the system’s display adapter.

SETPIXELSRGB sets the pixels specified in the arrays x and y to the RGB color values in color. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three color values, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you set with SETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
+---------------------+---------------------+
| MSB | LSB                 |
| 31   | 0                   |
| 24   | 8                   |
| 23   | 7                   |
| 16   | 15                  |
| 15   |                      |
| 8    | 7                   |
| 7    | 0                   |
| 0    | 0                   |
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

A good use for SETPIXELSRGB is as a buffering form of SETPIXELRGB, which can improve performance substantially. The example code shows how to do this.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELSRGB with n less than 1 are also ignored.

SETPIXELSRGB (and the other RGB color selection functions such as SETPIXELRGB and SETCOLORRGB) sets colors to values chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.
If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS   QUICKWIN GRAPHICS   LIB

**See Also:** "GETPIXELSRGB", "SETPIXELRGB, SETPIXELRGB_W", "GETPIXELRGB, GETPIXELRGB_W", "SETPIXELS"

**Example**

! Buffering replacement for SetPixelRGB and
! SetPixelRGB_W. This can improve performance by
! doing batches of pixels together.

USE IFQWIN
PARAMETER (I$SIZE = 200)
INTEGER(4) bn, bc(I$SIZE), status
INTEGER(2) bx(I$SIZE),by(I$SIZE)

bn = 0
DO i = 1, I$SIZE
   bn = bn + 1
   bx(bn) = i
   by(bn) = i
   bc(bn) = GETCOLORRGB()
   status = SETCOLORRGB(bc(bn)+1)
END DO
CALL SETPIXELSRGB(bn,bx,by,bc)
END

**SETTEXTCOLOR**

**Graphics Function:** Sets the current text color index. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

result = SETTEXTCOLOR (index)
index
(Input) INTEGER(2). Color index to set the text color to.

Results:
The result type is INTEGER(2). The result is the previous text color index.
SETTEXTCOLOR sets the current text color index. The default value is 15, which is associated with white unless the user remaps the palette. GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT.
The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

NOTE. The SETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetTextColor. For more information, see "Special Naming Convention for Certain QuickWin and Win32 Graphics Routines" in Building Applications.

Compatibility
STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: “GETTEXTCOLOR”, “REMAPPALETTERGB”, “SETCOLOR”, “SETTEXTCOLORRGB”

Example
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) oldtc
oldtc = SETTEXTCOLOR(INT2(2)) ! green
WRITE(*,*) "hello, world"
END
SETTEXTCOLORRGB

**Graphics Function:** Sets the current text color to the specified Red-Green-Blue (RGB) value. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```plaintext
result = SETTEXTCOLORRGB (color)
```

**color**

(Input) INTEGER(4). RGB color value to set the text color to. Range and result depend on the system’s display adapter.

**Results:**

The result type is INTEGER(4). The result is the previous text RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RGB</strong></td>
<td>00000000</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>B</td>
<td>G</td>
<td>G</td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z’FF’) the maximum for each of the three components. For example, Z’0000FF’ yields full-intensity red, Z’00FF00’ full-intensity green, Z’FF0000’ full-intensity blue, and Z’FFFFFF’ full-intensity for all three, resulting in bright white.

SETTEXTCOLORRGB sets the current text RGB color. The default value is Z’00FFFFFF’, which is full-intensity white. SETTEXTCOLORRGB sets the color used by OUTTEXT, WRITE, and PRINT. It does not affect the color of text output with the OUTGTEXT font routine. Use SETCOLORRGB to change the color of font output.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETCOLORRGB sets the RGB color value of graphics over the background color, used by the graphics functions such as ARC, FLOODFILLRGB, and OUTGTEXT.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values.
If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also:** "SETBKCOLORRGB", "SETCOLORRGB", "GETTEXTCOLORRGB", "GETWINDOWCONFIG", "OUTTEXT"

**Example**

```fortran
! Build as a Graphics ap.
USE IFQWIN
INTEGER(4) oldtc

oldtc = SETTEXTCOLORRGB(Z'000000FF')
WRITE(*,*) 'I am red'
oldtc = SETTEXTCOLORRGB(Z'0000FF00')
CALL OUTTEXT ('I am green'//CHAR(13)//CHAR(10))
oldtc = SETTEXTCOLORRGB(Z'00FF0000')
PRINT *, 'I am blue'
END
```

**SETTEXTCURSOR**

**Graphics Function:** Sets the height and width of the text cursor (the caret) for the window in focus. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = SETTEXTCURSOR (newcursor)
```

**newcursor**

(Input) INTEGER(2). The leftmost 8 bits specify the width of the cursor, and the rightmost 8 bits specify the height of the cursor. These dimensions can range from 1 to 8, and represent a fraction of the current character cell size. For example:

- Z'0808' – Specifies the full character cell; this is the default size.
- Z'0108' – Specifies 1/8th of the character cell width, and 8/8th (or all) of the character cell height.

If either of these dimensions is outside the range 1 to 8, it is forced to 8.
Results:
The result type is INTEGER(2); it is the previous text cursor value in the same format as newcursor.

NOTE. After calling SETTEXTCURSOR, you must call DISPLAYCURSOR($GCURSORON) to actually see the cursor.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “DISPLAYCURSOR”

Example
use IFQWIN
integer(2) oldcur
integer(2) istat
type(rccoord) rc
open(10, file='user')
istat = displaycursor($GCURSORON)
write(10,*), 'Text cursor is now character cell size, the default.'
read(10,*)
write(10,*), 'Setting text cursor to wide and low.'
oldcur = settextcursor(Z'0801')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*), 'Setting text cursor to high and narrow.'
oldcur = settextcursor(Z'0108')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*), 'Setting text cursor to a dot.'
oldcur = settextcursor(Z'0101')
istat = displaycursor($GCURSORON)
read(10,*)
end
SETTEXTPOSITION

Graphics Subroutine: Sets the current text position to a specified position relative to the current text window. This subroutine is only available on Windows* systems.

Module: USE IFQWIN

Syntax

CALL SETTEXTPOSITION (row, column, t)

row (Input) INTEGER(2). New text row position.
column (Input) INTEGER(2). New text column position.
t (Output) Derived type rccoord. Previous text position. The derived type rccoord is defined in IFQWIN.F90 as follows:

TYPE rccoord
  INTEGER(2) row ! Row coordinate
  INTEGER(2) col ! Column coordinate
END TYPE rccoord

Subsequent text output with the OUTTEXT function (as well as standard console I/O statements, such as PRINT and WRITE) begins at the point (row, column).

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “CLEARSCREEN”, “GETTEXTPOSITION”, “OUTTEXT”, “SCROLLTEXTWINDOW”, “SETEXTWINDOW”, “WRAPON”

Example

USE IFQWIN

TYPE (rccoord) curpos

WRITE(*,*) "Original text position"
CALL SETTEXTPOSITION (INT2(6), INT2(5), curpos)
WRITE (*,*) 'New text position'
END
SETTEXTWINDOW

**Graphics Subroutine:** Sets the current text window. This subroutine is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
CALL SETTEXTWINDOW (r1, c1, r2, c2)
```

- `r1, c1` (Input) INTEGER(2). Row and column coordinates for upper-left corner of the text window.
- `r2, c2` (Input) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

SETTEXTWINDOW specifies a window in row and column coordinates where text output to the screen using OUTTEXT, WRITE, or PRINT will be displayed. You set the text location within this window with SETTEXTPOSITION.

Text is output from the top of the window down. When the window is full, successive lines overwrite the last line.

SETTEXTWINDOW does not affect the output of the graphics text routine OUTGTEXT. Use the SETVIEWPORT function to control the display area for graphics output.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

**See Also:** "GETTEXTPOSITION", "GETTEXTWINDOW", "GRSTATUS", "OUTTEXT", "SCROLLTEXTWINDOW", "SETTEXTPOSITION", "SETVIEWPORT", "WRAPON"

**Example**

```fortran
USE IFQWIN
TYPE (rccoord) curpos

CALL SETTEXTWINDOW(INT2(5), INT2(1), INT2(7), INT2(40))
CALL SETTEXTPOSITION (INT2(5), INT2(5), curpos)
WRITE(*,*) "Only two lines in this text window"
WRITE(*,*) "so this line will be overwritten"
WRITE(*,*) "by this line"
END
```
SETTIM

**Portability Function:** Sets the system time in your programs. This function is only available on Windows® and Linux® systems.

**Module:** USE IFPORT

**Syntax**

\[
\text{result} = \text{SETTIM} \left( ihr, \text{imin}, \text{isec}, i100th \right)
\]

- **ihr**
  (Input) INTEGER(4) or INTEGER(2). Hour (0-23).
- **imin**
  (Input) INTEGER(4) or INTEGER(2). Minute (0-59).
- **isec**
  (Input) INTEGER(4) or INTEGER(2). Second (0-59).
- **i100th**
  (Input) INTEGER(4) or INTEGER(2). Hundredth of a second (0-99).

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

---

**NOTE.** On Linux systems, you must have root privileges to execute this function.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL  LIB

**See Also:** “GETDAT”, “GETTIM”, “SETDAT”

**Example**

USE IFPORT

LOGICAL(4) success

success = SETTIM(INT2(21), INT2(53+3), &
  INT2(14*2), INT2(88))

END
SETVIEWORG

**Graphics Subroutine:** Moves the viewport-coordinate origin (0, 0) to the specified physical point. This subroutine is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
CALL SETVIEWORG (x, y, t)
```

**x, y**

(Input) INTEGER(2). Physical coordinates of new viewport origin.

**t**

(Output) Derived type `xycoord`. Physical coordinates of the previous viewport origin. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord ! x-coordinate
  INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord
```

The `xycoord` type variable `t`, defined in `IFQWIN.F90`, returns the physical coordinates of the previous viewport origin.

**Compatibility**

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETCURRENTPOSITION, GETCURRENTPOSITION_W", "GETPHYSCOORD", "GETVIEWCOORD, GETVIEWCOORD_W", "GETWINDOWCOORD", "GRSTATUS", "SETCLIPRGN", "SETVIEWPORT"

**Example**

```fortran
USE IFQWIN
TYPE (xycoord) xy

CALL SETVIEWORG(INT2(30), INT2(30), xy)
```

SETVIEWPORT

**Graphics Subroutine:** Redefines the graphics viewport by defining a clipping region in the same manner as SETCLIPRGN and then setting the viewport-coordinate origin to the upper-left corner of the region. This subroutine is only available on Windows® systems.

**Module:** USE IFQWIN
Syntax

CALL SETVIEWPORT (x1, y1, x2, y2)

x1, y1
(Input) INTEGER(2). Physical coordinates for upper-left corner of viewport.

x2, y2
(Input) INTEGER(2). Physical coordinates for lower-right corner of viewport.

The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangular clipping region. Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

Compatibility

STANDARD GRAPHICS  QUICKWIN GRAPHICS  LIB

See Also: "GETVIEWCOORD, GETVIEWCOORD_W", "GETPHYSCOORD", "GRSTATUS", "SETCLIPRGN", "SETVIEWORG", "SETWINDOW"

Example

USE IFQWIN
INTEGER(2) upx, upy
INTEGER(2) downx, downy

upx = 0
upy = 30
downx= 250
downy = 100
CALL SETVIEWPORT(upx, upy, downx, downy)

SETWINDOW

Graphics Function: Defines a window bound by the specified coordinates. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = SETWINDOW (finvert, wx1, wy1, wx2, wy2)

finvert
(Input) LOGICAL(2). Direction of increase of the y-axis. If finvert is .TRUE., the y-axis increases from the window bottom to the window top (as Cartesian coordinates). If finvert is .FALSE., the y-axis increases from the window top to the window bottom (as pixel coordinates).
Descriptions of the Library Routines

**SETWINDOW**

**wx1, wy1**

(Input) REAL(8). Window coordinates for upper-left corner of window.

**wx2, wy2**

(Input) REAL(8). Window coordinates for lower-right corner of window.

**Results:**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0 (for example, if the program that calls SETWINDOW is not in a graphics mode).

The SETWINDOW function determines the coordinate system used by all window-relative graphics routines. Any graphics routines that end in _W (such as ARC_W, RECTANGLE_W, and LINETO_W) use the coordinate system set by SETWINDOW.

Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

An arc drawn using inverted window coordinates is not an upside-down version of an arc drawn with the same parameters in a noninverted window. The arc is still drawn counterclockwise, but the points that define where the arc begins and ends are inverted.

If \( \text{wx1} \) equals \( \text{wx2} \) or \( \text{wy1} \) equals \( \text{wy2} \), SETWINDOW fails.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also:

“GETWINDOWCOORD”, “SETCLIPRGN”, “SETVIEWORG”, “SETVIEWPORT”, “GRSTATUS”

**Example**

USE IFQWIN

INTEGER(2) status

LOGICAL(2) invert /.TRUE./

REAL(8) upx /0.0/, upy /0.0/

REAL(8) downx /1000.0/, downy /1000.0/

status = SETWINDOW(invert, upx, upy, downx, downy)

**SETWINDOWCONFIG**

**QuickWin Function:** Sets the properties of a child window. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

result = SETWINDOWCONFIG (wc)
(Input) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE windowconfig
  INTEGER(2) numxpixels             ! Number of pixels on x-axis.
  INTEGER(2) numypixels             ! Number of pixels on y-axis.
  INTEGER(2) numtextcols        ! Number of text columns available.
  INTEGER(2) numtextrows        ! Number of text rows available.
  INTEGER(2) numcolors              ! Number of color indexes.
  INTEGER(4) fontsize           ! Size of default font. Set to
  ! QWIN$EXTENDFONT when specifying    ! extended attributes, in which
  ! case extendfontsize sets the
  ! font size.
  CHARACTER(80) title              ! The window title.
  INTEGER(2) bitsperpixel       ! The number of bits per pixel.
  INTEGER(2) numvideopages         ! Unused.
  INTEGER(2) mode               ! Controls scrolling mode (see
  ! wc%mode below).
  INTEGER(2) adapter               ! Unused.
  INTEGER(2) monitor               ! Unused.
  INTEGER(2) memory                ! Unused.
  INTEGER(2) environment           ! Unused.
  ! The next three parameters provide extended font
  ! attributes.
  CHARACTER(32) extendfontname     ! The name of the desired font.
  INTEGER(4) extendfontsize     ! Takes the same values as fontsize,
  ! when fontsize is set to
  ! QWIN$EXTENDFONT.
  INTEGER(4) extendfontattributes   ! Font attributes such as bold
  ! and italic.
END TYPE windowconfig

Results:
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
The following value can be used to configure a QuickWin window so that it will show the last line
written and the text cursor (if it is on):
  wc%mode = QWIN$SCROLLDOWN
Be aware that if you scroll the window to another position, you will have to scroll back to the last line to see your input.

The following values can be used with SETWINDOWCONFIG extended fonts:

**Style:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_NORMAL</th>
<th>Gives no underline, no italic, and a font weight of 400 out of 1000.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_UNDERLINE</td>
<td>Gives underlined characters.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_BOLD</td>
<td>Gives a font weight of 700 out of 1000.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_ITALIC</td>
<td>Gives italic characters.</td>
</tr>
</tbody>
</table>

**Pitch:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_FIXED_PITCH</th>
<th>QuickWin default. Equal character widths.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_VARIABLE_PITCH</td>
<td>Variable character widths.</td>
</tr>
</tbody>
</table>

**Font Families:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_FF_ROMAN</th>
<th>Variable stroke width, serifed. Times Roman, Century Schoolbook, etc.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FF_SWISS</td>
<td>Variable stroke width, sans-serifed. Helvetica, Swiss, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_MODERN</td>
<td>QuickWin default. Constant stroke width, serifed or sans-serifed. Pica, Elite, Courier, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SCRIPT</td>
<td>Cursive, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_DECORATIVE</td>
<td>Old English, etc.</td>
</tr>
</tbody>
</table>

**Character Sets:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_ANSI_CHARSET</th>
<th>QuickWin default.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_OEM_CHARSET</td>
<td>Use this to get Microsoft* LineDraw.</td>
</tr>
</tbody>
</table>

Using QWIN$EXTENDFONT_OEM_CHARSET with the font name 'MS LineDrawC will get the old DOS-style character set with symbols that can be used to draw lines and boxes. The pitch and font family items can be specified to help guide the font matching algorithms used by CreateFontIndirect, the Windows* API used by SETWINDOWCONFIG.

If you use SETWINDOWCONFIG to set the variables in windowconfig to –1, the function sets the highest resolution possible for your system, given the other fields you specify, if any. You can set the actual size of the window by specifying parameters that influence the window size: the number of x and y pixels, the number of rows and columns, and the font size. If you do not call SETWINDOWCONFIG, the window defaults to the best possible resolution and a font size of 8x16. The number of colors available depends on the video driver used.
If you use SETWINDOWCONFIG, you should specify a value for each field (–1 or your own value for the numeric fields and a C string for the title, for example, "words of text"C). Using SETWINDOWCONFIG with only some fields specified can result in useless values for the unspecified fields.

If you request a configuration that cannot be set, SETWINDOWCONFIG returns .FALSE. and calculates parameter values that will work and are as close as possible to the requested configuration. A second call to SETWINDOWCONFIG establishes the adjusted values; for example:

```fortran
status = SETWINDOWCONFIG(wc)
if (.NOT.status) status = SETWINDOWCONFIG(wc)
```

If you specify values for all four of the size parameters, `numxpixels`, `numypixels`, `numtextcols`, and `numtextrows`, the font size is calculated by dividing these values. The default font is Courier New and the default font size is 8x16. There is no restriction on font size, except that the window must be large enough to hold it.

Under Standard Graphics, the application attempts to start in Full Screen mode with no window decoration (window decoration includes scroll bars, menu bar, title bar, and message bar) so that the maximum resolution can be fully used. Otherwise, the application starts in a window. You can use `ALT+ENTER` at any time to toggle between the two modes.

If you are in Full Screen mode and the resolution of the window does not match the resolution of the video driver, graphics output will be slow compared to drawing in a window.

### Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also: “GETWINDOWCONFIG”, “DISPLAYCURSOR”, "Using QuickWin" in Building Applications

### Example

```fortran
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL status /.FALSE./
! Set the x & y pixels to 800X600 and font size to 8x12
wc%numxpixels  = 800
wc%numypixels  = 600
wc%numtextcols = -1
```

**NOTE.** You must call DISPLAYCURSOR($GCURSORON) to make the cursor visible after calling SETWINDOWCONFIG.
wc%numtextrows = -1
wc%numcolors = -1
wc%title = "This is a test"
c
wc%fontsize = Z'0008000C'

status = SETWINDOWCONFIG(wc) ! attempt to set configuration with above values
! if attempt fails, set with system estimated values
if (.NOT.status) status = SETWINDOWCONFIG(wc)

**SETWINDOWMENUQQ**

**QuickWin Function:** Sets a top-level menu as the menu to which a list of current child window names is appended. This function is only available on Windows* systems.

**Module:** USE IFQWIN

**Syntax**

```
result = SETWINDOWMENUQQ (menuID)
```

*menuID*

(Input) INTEGER(4). Identifies the menu to hold the child window names, starting with 1 as the leftmost menu.

**Results:**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.. The list of current child window names can appear in only one menu at a time. If the list of windows is currently in a menu, it is removed from that menu. By default, the list of child windows appears at the end of the Window menu.

**Compatibility**

QUICKWIN GRAPHICS LIB

**See Also:** "APPENDMENUQQ", "Using QuickWin" and "Customizing QuickWin Applications" in Building Applications,

**Example**

```
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL(4) result, status /.FALSE./
! Set title for child window
wc%numxpixels = -1
wc%numypixels = -1
wc%numtextcols = -1
```
wc%numtextrows = -1
wc%numcolors   = -1
wc%fontsize    = -1
wc%title= "I am child window name"C
if (.NOT.status) status = SETWINDOWCONFIG(wc)

! put child window list under menu 3 (View)
result = SETWINDOWMENUQQ(3)
END

SETWRITEMODE

Graphics Function: Sets the current logical write mode, which is used when drawing lines with
the LINETO, POLYGON, and RECTANGLE functions. This function is only available on
Windows* systems.

Module: USE IFQWIN

Syntax

result = SETWRITEMODE (wmode)

wmode
(Input) INTEGER(2). Write mode to be set. One of the following symbolic constants (defined in
IFQWIN.F90):

• $GPSET – Causes lines to be drawn in the current graphics color. (Default)
• $GAND – Causes lines to be drawn in the color that is the logical AND of the current
  graphics color and the current background color.
• $GOR – Causes lines to be drawn in the color that is the logical OR of the current graphics
  color and the current background color.
• $GPRESET – Causes lines to be drawn in the color that is the logical NOT of the current
  graphics color.
• $GXOR – Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the
  current graphics color and the current background color.

In addition, one of the following binary raster operation constants can be used (described in the
online documentation for the Windows* API SetROP2):

• $GR2_BLACK
• $GR2_NOTMERGEPEN
• $GR2_MASKNOTPEN
• $GR2_NOTCOPYPEN (same as $GPRESET)
• $GR2_MASKPENNOT
• $GR2_NOT
• $GR2_XORPEN (same as $GXOR)
• $GR2_NOTMASKPEN
• $GR2_MASKPEN (same as $GAND)
• $GR2_NOTXORPEN
• $GR2_NOP
• $GR2_MERGENOTPEN
• $GR2_COPYPEN (same as $GPSET)
• $GR2_MERGEPENNOT
• $GR2_MERGEPEN (same as $GOR)
• $GR2_WHITE

Results:
The result type is INTEGER(2). The result is the previous write mode if successful; otherwise, -1.

The current graphics color is set with SETCOLORRGB (or SETCOLOR) and the current background color is set with SETBKCOLORRGB (or SETBKCOLOR). As an example, suppose you set the background color to yellow (Z'00FFFF') and the graphics color to purple (Z'FF00FF') with the following commands:

oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')

If you then set the write mode with the $GAND option, lines are drawn in red (Z'0000FF'); with the $GOR option, lines are drawn in white (Z'FFFFFF'); with the $GXOR option, lines are drawn in turquoise (Z'FFFF00'); and with the $GPRESET option, lines are drawn in green (Z'00FF00'). Setting the write mode to $GPSET causes lines to be drawn in the graphics color.

Compatibility

See Also: "GETWRITEMODE", "GRSTATUS", "LINETO, LINETO_W", "POLYGON, POLYGON_W", "PUTIMAGE, PUTIMAGE_W", "RECTANGLE, RECTANGLE_W", "SETCOLOR", "SETLINESTYLE"

Example
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) result, oldmode
INTEGER(4) oldcolor
TYPE (xycoord) xy
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN ($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
CALL MOVETO(INT2(0), INT2(0), xy)
result = LINETO(INT2(200), INT2(200)) ! purple
oldmode = SETWRITEMODE( $GAND)
CALL MOVETO(INT2(50), INT2(0), xy)
result = LINETO(INT2(250), INT2(200)) ! red
END

SETWSIZEQQ

QuickWin Function: Sets the size and position of a window. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

\[
\text{result} = \text{SETWSIZEQQ}(\text{unit}, \text{winfo})
\]

\text{unit}

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5, and 6 refer to the default startup window only if the program does not explicitly open them with the OPEN statement. To set the size of the frame window (as opposed to a child window), set \text{unit} to the symbolic constant QWIN$FRAMEWINDOW (defined in IFQWIN.F90).

When called from INITIALSETTINGS, SETWSIZEQQ behaves slightly differently than when called from a user routine after initialization. See below under Results.

\text{winfo}

(Input) Derived type \text{qwinfo}. Physical coordinates of the window’s upper-left corner, and the current or maximum height and width of the window’s client area (the area within the frame). The derived type \text{qwinfo} is defined in IFQWIN.F90 as follows:

\[
\text{TYPE QWINFO}
\begin{align*}
\text{INTEGER(2) TYPE} & \quad ! \text{request type} \\
\text{INTEGER(2) X} & \quad ! \text{x coordinate for upper left} \\
\text{INTEGER(2) Y} & \quad ! \text{y coordinate for upper left} \\
\text{INTEGER(2) H} & \quad ! \text{window height} \\
\text{INTEGER(2) W} & \quad ! \text{window width}
\end{align*}
\text{END TYPE QWINFO}
\]
This function’s behavior depends on the value of QWINFO%TYPE, which can be any of the following:

- QWIN$MIN – Minimizes the window.
- QWIN$MAX – Maximizes the window.
- QWIN$RESTORE – Restores the minimized window to its previous size.
- QWIN$SET – Sets the window’s position and size according to the other values in qwinfo.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero (unless called from INITIALSETTINGS). If called from INITIALSETTINGS, the following occurs:

- SETWSIZEQQ always returns –1.
- Only QWIN$SET will work.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width specified for a frame window reflects the actual size in pixels of the frame window including any borders, menus, and status bar at the bottom.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: “GETWSIZEQQ”, “INITIALSETTINGS”, “Using QuickWin” in Building Applications

Example
USE IFQWIN
INTEGER(4)     result
INTEGER(2)     numfonts, fontnum
TYPE (qwinfo)   winfo
TYPE (xycoord)  pos
! Maximize frame window
winfo%TYPE = QWIN$MAX
result = SETWSIZEQQ(QWIN$FRAMEWINDOW, winfo)
! Maximize child window
result = SETWSIZEQQ(0, winfo)
numfonts = INITIALIZEFONTS( )
fontnum = SETFONT ('t''Arial''h50w34i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT("BIG Window")
END
SHORT

Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{SHORT (int4)}
\]

*int4*

(Input) INTEGER(4). Value to be converted.

Results:
The result type is INTEGER(2). The result is equal to the lower 16 bits of *int4*. If the *int4* value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: the INT intrinsic function and the TYPE statement in the Language Reference

Example

```
USE IFPORT
INTEGER(4) THIS_ONE
INTEGER(2) THAT_ONE
READ(*,*) THIS_ONE
THAT_ONE = SHORT(THIS_ONE)
WRITE(*,10) THIS_ONE, THAT_ONE
END
```

SIGNAL

Portability Function: Controls interrupt signal handling. Changes the action for a specified signal.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{SIGNAL (signum, proc, flag)}
\]

*signum*

(Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names for the signals are listed in a table below.
proc
(Input) Name of a signal-processing routine. It must be declared EXTERNAL. This routine is called only if flag is negative.

flag
(Input) INTEGER(4). If negative, the user’s proc routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.

Results:
The result type is INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. The result is the previous value of proc associated with the specified signal. For example, if the previous value of proc was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is invalid, if the flag value is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINV AL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns –(EINV AL) and a call to IERRNO returns EINV AL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C’s signal function; nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

All signal handlers are called with a single integer argument, that of the signal number actually received. Usually, when a process receives a signal, it terminates. With the SIGNAL function, a user procedure is called instead. The signal handler routine must accept the signal number integer argument, even if it does not use it. If the routine does not accept the signal number argument, the stack will not be properly restored after the signal handler has executed.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

• Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
• Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
• Functions that generate a system call (such as TIME).

The following table lists signal names and values:
The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SIGNALQQ”

**Example**

```fortran
USE IFPORT
EXTERNAL h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler. Return = ', iret1
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END
!
! Signal handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
WRITE(*,*) 'In signal handler for SIG$ABORT'
```

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SIGNALQQ”

**Example**

```fortran
USE IFPORT
EXTERNAL h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler. Return = ', iret1
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END
!
! Signal handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
WRITE(*,*) 'In signal handler for SIG$ABORT'
```

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SIGNALQQ”

**Example**

```fortran
USE IFPORT
EXTERNAL h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler. Return = ', iret1
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END
!
! Signal handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
WRITE(*,*) 'In signal handler for SIG$ABORT'
```
WRITE(*,*) 'signum = ', sig_num
h_abort = 1
END

SIGNALQQ

Portability Function: Registers the function to be called if an interrupt signal occurs.
Module: USE IFPORT
Syntax
    result = SIGNALQQ (sig, func)

sig
(Input) INTEGER(2). Interrupt type. One of the following constants, defined in IFPORT.F90:
- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+C SIGNAL
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

func
(Input) Function to be executed on interrupt. It must be declared EXTERNAL.
Results:
The result type is INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. The result is a positive integer if successful; otherwise, –1 (SIG$ERR).
SIGNALQQ installs the function func as the handler for a signal of the type specified by sig. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.
The argument func is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

NOTE. All signal-handler functions must be declared with the cDECS ATTRIBUTES C option.
When an interrupt occurs, except a SIG$FPE interrupt, the `sig` argument SIG$INT is passed to `func`, and then `func` is executed.

When a SIG$FPE interrupt occurs, the function `func` is passed two arguments: SIG$FPE and the floating-point error code (for example, FPESERODIVIDE or FPESOVERTFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPES$ and are defined in `IFPORT.F90`. Floating-point exceptions are described and discussed in "The Floating-Point Environment" in Building Applications.

If `func` returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode.

Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).

To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.

The example below demonstrates a signal handler for SIG$ABORT. A sample signal handler for SIG$FPE is given in "Handling Floating-Point Exceptions" in Building Applications.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "RAISEQQ", "SIGNAL", "KILL", "GETEXCEPTIONPTrsQQ (i32, i32em)"

**Example**

```fortran
! This program shows a signal handler for
! SIG$ABORT
USE IFPORT
INTERFACE
  FUNCTION h_abort (signum)
    !DEC$ ATTRIBUTES C :: h_abort
    INTEGER(4) h_abort
    INTEGER(2) signum
  END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret
```
i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret

i2ret = RAISEQQ(SIG$ABORT)
WRITE(*,*) 'Raised signal. Return = ', i2ret
END
!
!  Signal handler routine
!
INTEGER(4) FUNCTION h_abort (signum)
!DEC$ ATTRIBUTES C :: h_abort
INTEGER(2) signum
WRITE(*,*) 'In signal handler for SIG$ABORT'
WRITE(*,*) 'signum = ', signum
h_abort = 1
END

SLEEP

Portability Subroutine: Suspends the execution of a process for a specified interval.
Module: USE IFPORT
Syntax
    CALL SLEEP (time)

    time
(Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also: “SLEEPQQ”
Example
USE IFPORT
integer(4) hold_time
hold_time = 1 !lets the loop execute
DO WHILE (hold_time .NE. 0)
    write(*,'(A)') "Enter the number of seconds to suspend"
    read(*,*) hold_time
    CALL SLEEP (hold_time)
SLEEPQQ

Portability Subroutine: Delays execution of the program for a specified duration.
Module: USE IFPORT
Syntax
   CALL SLEEPQQ (duration)
duration
(Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example
USE IFPORT
INTEGER(4) delay, freq, duration
delay    = 2000
freq     = 4000
duration = 1000
CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)
END

SORTQQ

Portability Subroutine: Sorts a one-dimensional array. The array elements cannot be derived types or record structures.
Module: USE IFPORT
Syntax
   CALL SORTQQ (adrarray, count, size)
adrarray
(Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Address of the array (returned by LOC).
count
(Input; output) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel
EM64T processors. On input, number of elements in the array to be sorted. On output, number of
elements actually sorted.

size
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be
sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric
arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in size is not a symbolic constant and is less than 32,767, the array is
assumed to be a character array with size characters per element.

To be certain that SORTQQ is successful, compare the value returned in count to the value you
provided. If they are the same, then SORTQQ sorted the correct number of elements.

CAUTION. The location of the array must be passed by address using the
LOC intrinsic function. This defeats Fortran type-checking, so you must make
certain that the count and size arguments are correct.

If you pass invalid arguments, SORTQQ attempts to sort random parts of
memory. If the memory it attempts to sort is allocated to the current process,
that memory is sorted; otherwise, the operating system intervenes, the program
is halted, and you get a General Protection Violation message.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "BSEARCHQQ", the LOC intrinsic function in the Language Reference
Example

!    Sort a 1-D array
!
USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i
DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 2223, 67/
!    Sort the array
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)
!    Display the sorted array
DO i = 1, 10
   WRITE (*, 9000) i, array (i)
9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END

SPLITPATHQQ

Portability Function: Breaks a file path or directory path into its components.
Module: USE IFPORT
Syntax

result = SPLITPATHQQ (path, drive, dir, name, ext)

path
(Input) Character*(*). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in path.

drive
(Output) Character*(*). Drive letter followed by a colon.

dir
(Output) Character*(*). Path of directories, including the trailing slash.

name
(Output) Character*(*). Name of file or, if no file is specified in path, name of the lowest directory. A file name must not include an extension.

ext
(Output) Character*(*). File name extension, if any, including the leading period (.).
Results:
The result type is INTEGER(4). The result is the length of dir.
The path parameter can be a complete or partial file specification.
$MAXPATH$ is a symbolic constant defined in module IFPORT.F90 as 260.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “FULLPATHQQ”

Example
USE IFPORT
CHARACTER($MAXPATH) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) length

buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext

END

SPORT_CANCEL_IO

Serial Port I/O Function: Cancels any I/O in progress to the specified port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax
    result = SPORTCANCEL_IO (port)

port
    (Input) Integer. The port number.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

NOTE. This call also kills the thread that keeps an outstanding read operation to the serial port. This call must be done before any of the port characteristics are modified.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB "

See Also: "Using the Serial I/O Port Routines" in *Building Applications*, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CANCEL_IO( 2 )
END

SPORT_CONNECT

Serial Port I/O Function: Establishes the connection to a serial port and defines certain usage parameters. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

result = SPORT_CONNECT (port [, options])

port

(Input) Integer. The port number of connection. The routine will open COMn, where n is the port number specified.

options

(Optional; input) Integer. Defines the connection options. These options define how the *nnn_LINE* routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
</tbody>
</table>
Descriptions of the Library Routines

If `options` is not specified, the following occurs by default:

- `(DL_OUT_CR .OR. DL_TERM_CR .OR. DL_TOSS_CR .OR. DL_TOSS_LF)`

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "SPORT_RELEASE", "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

**Example**

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT( 2 )
END
```

**SPORT_CONNECT_EX**

**Serial Port I/O Function:** Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception. This function is only available on Windows* systems.

**Module:** USE IFPORT

**Syntax**

```
result = SPORT_CONNECT_EX (port [, options] [, BufferSize])
```
port
(Input) Integer. The port number of connection. The routine will open COM\(n\), where \(n\) is the port number specified.

options
(Optional; input) Integer. Defines the connection options. These options define how the \(nnn\_LINE\) routines will work and also affect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes (SPORT_WRITE_LINE) to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes (SPORT_WRITE_LINE) to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes (SPORT_READ_LINE) to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>DL_TERM_LF</td>
<td>Causes (SPORT_READ_LINE) to terminate READ when a LF is encountered.</td>
</tr>
<tr>
<td>DL_TERM_CRLF</td>
<td>Causes (SPORT_READ_LINE) to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If \(options\) is not specified, the following occurs by default:

\[(DL\_OUT\_CR .OR. DL\_TERM\_CR .OR. DL\_TOSS\_CR .OR. DL\_TOSS\_LF)\]

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

BufferSize
(Optional; input) Integer. Size of the internal buffer for data reception. If \(BufferSize\) is not specified, the size of the buffer is 16384 bytes (the default).

The size of the buffer must be 4096 bytes or larger. If you try to specify a size smaller than 4096 bytes, your specification will be ignored and the buffer size will be set to 4096 bytes.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “\(SPORT\_CONNECT\)”,”“\(SPORT\_RELEASE\)”, "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft® Platform SDK
**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT_EX( 2, BufferSize = 8196 )
END
```

**SPORT_GET_HANDLE**

**Serial Port I/O Function:** Returns the Windows® handle associated with the communications port. This is the handle that was returned by the Windows API CreateFile. This function is only available on Windows systems.

**Module:** USE IFPORT

**Syntax**

```fortran
result = SPORT_GET_HANDLE (port, handle)
```

**port**

(Input) Integer. The port number.

**handle**

(Output) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. This is the Windows handle that was returned from CreateFile() on the serial port.

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "Using the Serial I/O Port Routines" in *Building Applications*, "Communications and Communications Functions" in the Microsoft® Platform SDK

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
INTEGER(KIND=INT_PTR_KIND( )) handle
iresult = SPORT_GET_HANDLE( 2, handle )
END
```
SPORT_GET_STATE

Serial Port I/O Function: Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

result = SPORT_GET_STATE (port [, baud] [, parity] [, dbits] [, sbits])

port
(Input) Integer. The port number.

baud
(Optional; output) Integer. The baud rate of the port.

parity
(Optional; output) Integer. The parity setting of the port (0 - 4 = no, odd, even, mark, space).

dbits
(Optional; output) Integer. The data bits for the port.

sbits
(Optional; output) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_SET_STATE”, "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions” in the Microsoft* Platform SDK

Example

USE IFPORT
INTEGER(4) iresult
INTEGER    baud
INTEGER    parity
INTEGER    dbits
INTEGER    sbits

iresult =  SPORT_GET_STATE( 2, baud, parity, dbits, sbits )
END
SPORT_GET_STATE_EX

Serial Port I/O Function: Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

port
(Input) Integer. The port number.

baud
(Optional; output) Integer. The baud rate of the port.

parity
(Optional; output) Integer. The parity setting of the port (0 - 4 = no, odd, even, mark, space).

dbits
(Optional; output) Integer. The data bits for the port.

sbits
(Optional; output) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Binmode
(Optional; output) Integer. 1 if binary mode is enabled; otherwise, 0. Currently, the value of this parameter is always 1.

DTRcntrl
(Optional; output) Integer. 1 if DTR (data-terminal-ready) flow control is used; otherwise, 0.

RTScntrl
(Optional; output) Integer. 1 if RTS (request-to-send) flow control is used; otherwise, 0.

OutCTSFlow
(Optional; output) Integer. 1 if CTS (clear-to-send) signal is monitored for output flow control; otherwise, 0.

OutDSRFlow
(Optional; output) Integer. 1 if DSR (data-set-ready) signal is monitored for output flow control; otherwise, 0.
DSRSense
(Optional; output) Integer. 1 if the communications driver is sensitive to the state of the DSR signal; otherwise, 0.

OutXonOff
(Optional; output) Integer. 1 if XON/XOFF flow control is used during transmission; otherwise, 0.

InXonOff
(Optional; output) Integer. 1 if XON/XOFF flow control is used during reception; otherwise, 0.

XonLim
(Optional; output) Integer. The minimum number of bytes accepted in the input buffer before the XON character is set.

XoffLim
(Optional; output) Integer. The maximum number of bytes accepted in the input buffer before the XOFF character is set.

TXContOnXoff
(Optional; output) Integer. 1 if transmission stops when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

ErrAbort
(Optional; output) Integer. 1 if read and write operations are terminated when an error occurs; otherwise, 0.

ErrCharEnbl
(Optional; output) Integer. 1 if bytes received with parity errors are replaced with the ErrChar character; otherwise, 0.

NullStrip
(Optional; output) Integer. 1 if null bytes are discarded; otherwise, 0.

XonChar
(Optional; output) Character. The value of the XON character that is used for both transmission and reception.

XoffChar
(Optional; output) Character. The value of the XOFF character that is used for both transmission and reception.
ErrChar
(Optional; output) Character. The value of the character that is used to replace bytes received with parity errors.

EofChar
(Optional; output) Character. The value of the character that is used to signal the end of data.

EvIChar
(Optional; output) Character. The value of the character that is used to signal an event.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_SET_STATE_EX”, "Using the Serial I/O Port Routines” in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
INTEGER(4) port, baud, parity, dbits, sbits
INTEGER(4) OutXonOff, InXonOff, OutDSRFlow
INTEGER(4) OutCTSFlow, DTRcntrl, RTScntrl
INTEGER(4) DSRSense, XonLim, XoffLim
CHARACTER(1) XonChar, XoffChar
iresult = SPORT_GET_STATE_EX(port, baud, parity, dbits, sbits, &
                            OutXonOff=OutXonOff, InXonOff=InXonOff, OutDSRFlow=OutDSRFlow, &
                            OutCTSFlow=OutCTSFlow, DTRcntrl=DTRcntrl, RTScntrl=RTScntrl, &
                            DSRSense = DSRSense, XonChar = XonChar, XoffChar = XoffChar, &
                            XonLim=XonLim, XoffLim=XoffLim)

END

SPORT_GET_TIMEOUTS
Serial Port I/O Function: Returns the user selectable timeouts for the serial port. This function is only available on Windows* systems.

Module: USE IFPORT
Syntax

result = SPORT_GET_TIMEOUTS (port [, rx_int] [, tx_tot_mult] [, tx_tot_const])

port
(Input) Integer. The port number.

rx_int
(Optional; output) INTEGER(4). The receive interval timeout value.

tx_tot_mult
(Optional; output) INTEGER(4). The transmit multiplier part of the timeout value.

tx_tot_const
(Optional; output) INTEGER(4). The transmit constant part of the timeout value.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "SPORT_SET_TIMEOUTS", "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft® Platform SDK

Example

USE IFPORT
INTEGER(4) iresult
INTEGER*4 rx_int
INTEGER*4 tx_tot_mult
INTEGER*4 tx_tot_const

iresult = SPORT_GET_TIMEOUTS( 2, rx_int, tx_tot_mult, tx_tot_const )
END

SPORT_PEEK_DATA

Serial Port I/O Function: Returns information about the availability of input data. This function is only available on Windows® systems.

Module: USE IFPORT

Syntax

result = SPORT_PEEK_DATA (port [, present] [, count])
port
(Input) Integer. The port number.

present
(Optional; output) Integer. 1 if data is present, 0 if no data has been read.

count
(Optional; output) Integer. The count of characters that will be returned by SPORT_READ_DATA.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

NOTE. CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "SPORT_CONNECT", "SPORT_READ_DATA", "SPORT_PEEK_LINE", "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
INTEGER    present
INTEGER    count

iresult =  SPORT_PEEK_DATA( 2, present, count )
END

SPORT_PEEK_LINE

Serial Port I/O Function: Returns information about the availability of input records. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax
result = SPORT_PEEK_LINE (port [, present] [, count])
port
(Input) Integer. The port number.

present
(Optional; output) Integer. 1 if data is present, 0 if no data has been read.

count
(Optional; output) Integer. The count of characters that will be returned by SPORT_READ_DATA.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT() call.

NOTE. CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT() call.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CONNECT”, “SPORT_READ_DATA”, “SPORT_PEEK_DATA”, "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions” in the Microsoft® Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
INTEGER present
INTEGER count

iresult = SPORT_PEEK_LINE( 2, present, count )
END

SPORT_PURGE

Serial Port I/O Function: Executes the Windows® API communications function PurgeComm on the specified port. This function is only available on Windows systems.

Module: USE IFPORT
Descriptions of the Library Routines

Syntax

result = SPORT_PURGE (port, function)

port
(Input) Integer. The port number.

function
(Input) INTEGER(4). The function for PurgeComm (see the Windows documentation).

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example
USE IFWINTY
USE IFPORT
INTEGER(4) iresult
iresult =  SPORT_PURGE( 2, (PURGE_TXABORT .or. PURGE_RXABORT) )
END

SPORT_READ_DATA

Serial Port I/O Function: Reads available data from the specified port. This routine stalls until at least one character has been read. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

result = SPORT_READ_DATA (port, buffer [, count])

port
(Input) Integer. The port number.

buffer
(Output) Character*(*)*. The data that was read.

count
(Optional; output) Integer. The count of bytes read.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

NOTE. CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT() call.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CONNECT”, “SPORT_PEEK_DATA”, “SPORT_READ_LINE”, “SPORT_WRITE_DATA”. "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example
USE IFPORT
INTEGER(4)      iresult
INTEGER         count
CHARACTER*1024  rbuff

iresult = SPORT_READ_DATA( 2, rbuff, count )
END

SPORT_READ_LINE

Serial Port I/O Function: Reads a record from the specified port. This routine stalls until at least one record has been read. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax
  result = SPORT_READ_LINE (port, buffer [, count])

port
  (Input) Integer. The port number.

buffer
  (Output) Character*(*). The data that was read.

count
  (Optional; output) Integer. The count of bytes read.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
This routine will only return when a line terminator has been seen – as defined by the mode specified in the SPORT_CONNECT( ) call.

NOTE. CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CONNECT”, “SPORT_PEEK_LINE”, “SPORT_READ_DATA”, “SPORT_WRITE_LINE”, "Using the Serial I/O Port Routines” in Building Applications, "Communications and "Communications Functions" in the Microsoft® Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
INTEGER count
CHARACTER*1024 rbuff

iresult = SPORT_READ_LINE( 2, rbuff, count )
END

SPORT_RELEASE

Serial Port I/O Function: Releases a serial port that was previously connected to (by using SPORT_CONNECT). This function is only available on Windows* systems.

Module: USE IFPORT

Syntax
result = SPORT_RELEASE(port)

port
(Input) Integer. The port number.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
Compatiblity
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CONNECT”, "Using the Serial I/O Routines” in Building Applications, "Communications and "Communications Functions” in the Microsoft* Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_RELEASE( 2 )
END

SPORT_SET_STATE

Serial Port I/O Function: Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax
result = SPORT_SET_STATE (port [, baud] [, parity] [, dbits] [, sbits])

port
(Input) Integer. The port number.

baud
(Optional; input) Integer. The baud rate of the port.

parity
(Optional; input) Integer. The parity setting of the port (0 – 4 = no, odd, even, mark, space).

dbits
(Optional; input) Integer. The data bits for the port.

sbits
(Optional; input) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
The following restrictions apply:
• The number of data bits must be 5 to 8 bits.
• The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.
**NOTE.** This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call `SPORT_CANCEL_IO` before port parameters can be changed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "SPORT_CANCEL_IO", "SPORT_GET_STATE", "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult =  SPORT_SET_STATE( 2, 9600, 0, 7, 1 )
END
```

**SPORT_SET_STATE_EX**

**Serial Port I/O Function:** Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port. This function is only available on Windows* systems.

**Module:** USE IFPORT

**Syntax**

```fortran
```

- `port` (Input) Integer. The port number.
- `baud` (Optional; input) Integer. The baud rate of the port.
- `parity` (Optional; input) Integer. The parity setting of the port (0 - 4 = no, odd, even, mark, space).
\( dbits \)
(Optional; input) Integer. The data bits for the port.

\( sbits \)
(Optional; input) Integer. The stop bits for the port \((0, 1, 2 = 1, 1.5, 2)\).

\( Binmode \)
(Optional; input) Integer. 1 if binary mode should be enabled; otherwise, 0. Currently, if this parameter is used, the value must be 1.

\( DTRcntrl \)
(Optional; input) Integer. 1 if DTR (data-terminal-ready) flow control should be used; otherwise, 0.

\( RTScntrl \)
(Optional; input) Integer. 1 if RTS (request-to-send) flow control should be used; otherwise, 0.

\( OutCTSFlow \)
(Optional; input) Integer. 1 if the CTS (clear-to-send) signal should be monitored for output flow control; otherwise, 0.

\( OutDSRFlow \)
(Optional; input) Integer. 1 if the DSR (data-set-ready) signal should be monitored for output flow control; otherwise, 0.

\( DSRSense \)
(Optional; input) Integer. 1 if the communications driver should be sensitive to the state of the DSR signal; otherwise, 0.

\( OutXonOff \)
(Optional; input) Integer. 1 if XON/XOFF flow control should be used during transmission; otherwise, 0.

\( InXonOff \)
(Optional; input) Integer. 1 if XON/XOFF flow control should be used during reception; otherwise, 0.

\( XonLim \)
(Optional; input) Integer. The minimum number of bytes that should be accepted in the input buffer before the XON character is set.

\( XoffLim \)
(Optional; input) Integer. The maximum number of bytes that should be accepted in the input buffer before the XOFF character is set.
Descriptions of the Library Routines

TXContOnXoff
(Optional; input) Integer. 1 if transmission should be stopped when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

ErrAbort
(Optional; input) Integer. 1 if read and write operations should be terminated when an error occurs; otherwise, 0.

ErrCharEnbl
(Optional; input) Integer. 1 if bytes received with parity errors should be replaced with the ErrChar character; otherwise, 0.

NullStrip
(Optional; input) Integer. 1 if null bytes should be discarded; otherwise, 0.

XonChar
(Optional; input) Character. The value of the XON character that should be used for both transmission and reception.

XoffChar
(Optional; input) Character. The value of the XOFF character that should be used for both transmission and reception.

ErrChar
(Optional; input) Character. The value of the character that should be used to replace bytes received with parity errors.

EofChar
(Optional; input) Character. The value of the character that should be used to signal the end of data.

EvtChar
(Optional; input) Character. The value of the character that should be used to signal an event.

fZeroDCB
(Optional; input) Integer. 1 if all settings of the communications port should be set to zero before parameters are set; otherwise, 0.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
The following restrictions apply:
• The number of data bits must be 5 to 8 bits.
The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

NOTE. This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CANCEL_IO”, “SPORT_GET_STATE_EX”, "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions” in the Microsoft* Platform SDK

Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_STATE_EX( 2, 9600, 0, 7, 1, OutXonOff=1, InXonOff=1, &
XonLim=1024, XoffLim=512, XonChar=CHAR(17), XoffChar=CHAR(19), &
fZeroDCB=1) )

END

SPORT_SET_TIMEOUTS

Serial Port I/O Function: Sets the user selectable timeouts for the serial port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

result = SPORT_SET_TIMEOUTS (port [, rx_int] [, tx_tot_mult] [, tx_tot_const])

port
(Input) Integer. The port number.

rx_int
(Optional; input) INTEGER(4). The receive interval timeout value.

tx_tot_mult
(Optional; input) INTEGER(4). The transmit multiplier part of the timeout value.
**tx_tot_const**

(Optional; input) INTEGER(4). The transmit constant part of the timeout value.

**Results:**
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

---

**NOTE.** This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call `SPORT_CANCEL_IO` before port parameters can be changed.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** "SPORT_CANCEL_IO", "SPORT_GET_STATE_EX", "Using the Serial I/O Port Routines" in *Building Applications*, "Communications and "Communications Functions" in the Microsoft* Platform SDK

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_TIMEOUTS( 2, 100, 0, 1000 )
END
```

---

**SPORT_SHOW_STATE**

**Serial Port I/O Function:** Displays the state of a port to standard output. This function is only available on Windows* systems.

**Module:** USE IFPORT

**Syntax**

```fortran
result = SPORT_SHOW_STATE (port, level)
```

**port**

(Input) Integer. The port number.

**level**

(Input) Integer. Controls the level of detail displayed as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Basic one line display</td>
</tr>
<tr>
<td>1</td>
<td>Basic information</td>
</tr>
</tbody>
</table>
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

**NOTE.** This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

### Compatibility

<table>
<thead>
<tr>
<th>CONSOLE</th>
<th>STANDARD GRAPHICS</th>
<th>QUICKWIN GRAPHICS</th>
<th>WINDOWS</th>
<th>DLL</th>
<th>LIB</th>
</tr>
</thead>
</table>

### See Also:

“SPORT_CANCEL_IO”, "Using the Serial I/O Routines” in *Building Applications*, "Communications and "Communications Functions” in the Microsoft* Platform SDK

### Example

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SHOW_STATE( 2, 0 )
END
```

## SPORT_SPECIAL_FUNC

**Serial Port I/O Function:** Executes the Windows* API communications function EscapeCommFunction on the specified port. This function is only available on Windows systems.

**Module:** USE IFPORT

**Syntax**

```fortran
result = SPORT_SPECIAL_FUNC (port, function)
```

- **port**
  - (Input) Integer. The port number.
function
(Input) INTEGER(4). The function to perform.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "Using the Serial I/O Port Routines" in Building Applications, "Communications and Communications Functions" in the Microsoft® Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SPECIAL_FUNC( 2, ? )
END

SPORT_WRITE_DATA

Serial Port I/O Function: Outputs data to the specified port. This function is only available on Windows® systems.

Module: USE IFPORT

Syntax
result = SPORT_WRITE_DATA (port, data [, count])

port
(Input) Integer. The port number.

data
(Input) Character*(*) . The data to be output.

count
(Optional; input) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
NOTE. When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter "count" contains the number of bytes that were really written.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: "SPORT_WRITE_LINE", "SPORT_READ_DATA", "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example

USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_DATA( 2, 'ATZ'//CHAR(13), 0 )
END

SPORT_WRITE_LINE

Serial Port I/O Function: Outputs data, followed by a record terminator, to the specified port. This function is only available on Windows* systems.

Module: USE IFPORT

Syntax

result = SPORT_WRITE_LINE (port, data [, count])

port
(Input) Integer. The port number.

data
(Input) Character*(*). The data to be output.

count
(Optional; input) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.
Results:
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
After the data is output, a line terminator character is added based on the mode used during the SPORT_CONNECT() call.

NOTE. When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter "count" contains the number of bytes that were really written.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SPORT_CONNECT”, “SPORT_WRITE_DATA”, “SPORT_READ_DATA”, "Using the Serial I/O Port Routines" in Building Applications, "Communications and "Communications Functions" in the Microsoft* Platform SDK

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_LINE( 2, 'ATZ', 0 )
END

SRAND
Portability Subroutine: Seeds the random number generator used with IRAND and RAND.
Module: USE IFPORT
Syntax
    CALL SRAND (iseed)
iseed
(Input) INTEGER(4), Any value. The default value is 1.
SRAND seeds the random number generator used with IRAND and RAND. Calling SRAND is equivalent to calling IRAND or RAND with a new seed.
The same value for isned generates the same sequence of random numbers. To vary the sequence, call SRAND with a different isned value each time the program is executed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL LIB

See Also: “RAND, RANDOM”, “IRAND, IRANDM”, the RANDOM_NUMBER and RANDOM_SEED intrinsic subroutines in the Language Reference

Example

! How many random numbers out of 100 will be between .5 and .6?
USE IFPORT
ICOUNT = 0
CALL SRAND(123)
DO I = 1, 100
   X = RAND(0)
   IF (X > .5).AND.(X < .6) ICOUNT = ICOUNT + 1
END DO
WRITE(*,*) ICOUNT, "numbers between .5 and .6!"
END

SSWRQQ

Portability Subroutine: Returns the floating-point processor status word.

Module: USE IFPORT
Syntax
   CALL SSWRQQ (status)
status
   (Output) INTEGER(2). Floating-point processor status word.
SSWRQQ performs the same function as the run-time subroutine GETSTATUSFPQQ and is provided for compatibility.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS  DLL LIB

See Also: “LCWRQQ”, “GETSTATUSFPQQ”

Example

USE IFPORT
INTEGER(2) status
CALL SSWRQQ (status)
STAT

**Portability Function:** Returns detailed information about a file.

**Module:** USE IFPORT

**Syntax**

```plaintext
result = STAT (name, statb)
```

- **name**
  - (Input) Character*. Name of the file to examine.

- **statb**
  - (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of `statb` contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W<em>32, W</em>64: Always 0; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W<em>32, W</em>64: Always 0; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(3)</td>
<td>Access mode of the file</td>
<td>See the table in Results</td>
</tr>
<tr>
<td>statb(4)</td>
<td>Number of hard links to the file</td>
<td>W<em>32, W</em>64: Always 1; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(5)</td>
<td>User ID of owner</td>
<td>W<em>32, W</em>64: Always 1; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>

<td>Group ID of owner</td>
<td>W<em>32, W</em>64: Always 1; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(7)</td>
<td>Raw device the file resides on</td>
<td>W<em>32, W</em>64: Always 0; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td>W<em>32, W</em>64: Only available on non-FAT file systems; undefined on FAT systems; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed</td>
<td>W<em>32, W</em>64: Only available on non-FAT file systems; undefined on FAT systems; L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified</td>
<td>W<em>32, W</em>64: Same as stat(10); L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change</td>
<td>W<em>32, W</em>64: Same as stat(10); L<em>X, M</em>X32: System dependent</td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W<em>32, W</em>64: Always 1; L<em>X, M</em>X32: System dependent</td>
</tr>
</tbody>
</table>

---

1. Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).
Results:
The result type is INTEGER(4).

On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code
ENOENT (the specified file could not be found). On Linux* and Mac OS* systems, the file
inquired about must be currently connected to a logical unit and must already exist when STAT is
called; if STAT fails, errno is set.

For a list of other error codes, see “IERRNO”.

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following
constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Constant</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows systems, LSTAT returns exactly the same information as STAT. On Linux and Mac OS systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

You can also use the INQUIRE statement to get information about file properties.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “GETFILEINFOQQ”, the INQUIRE statement in the Language Reference

**Example**

```fortran
USE IFPORT
CHARACTER*12 file_name
INTEGER(4) info_array(12)
print *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
   print *, info_array
else
   print *, 'Error = ', istatus
end if
```

**SYSTEM**

**Portability Function:** Sends a command to the shell as if it had been typed at the command line.

**Module:** USE IFPORT

### Symbolic name

<table>
<thead>
<tr>
<th>Symbolic name</th>

<td>Same as S_IRUSR on Windows systems</td>
</tr>
<tr>
<td>S_IWOTH</td>
<td>O'0000002'</td>
<td>Other's write permission</td>
<td>Same as S_IWUSR on Windows systems</td>
</tr>
<tr>
<td>S_IXOTH</td>
<td>O'0000001'</td>
<td>Other's execute permission</td>
<td>Same as S_IXUSR on Windows systems</td>
</tr>
</tbody>
</table>
Syntax

\[
\text{result} = \text{SYSTEM}(\text{string})
\]

\text{string}

(Input) Character\(^*(\*)\). Operating system command.

Results:

The result type is INTEGER(4). The result is the exit status of the shell command. If –1, use “IERRNO” to retrieve the error. Errors can be one of the following:

- E2BIG – The argument list is too long.
- ENOENT – The command interpreter cannot be found.
- ENOEXEC – The command interpreter file has an invalid format and is not executable.
- ENOMEM – Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows* API CreateProcess() in your Fortran code.

Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SYSTEMQQ”

Example

USE IFPORT

INTEGER(4) I, errnum

I = SYSTEM("dir > file.lst")

If (I .eq. -1) then

    errnum = ierrno()
    print *, 'Error ', errnum

end if

END
SYSTEMQQ

Portability Function: Executes a system command by passing a command string to the operating system’s command interpreter.

Module: USE IFPORT

Syntax

\[
\text{result} = \text{SYSTEMQQ} (\text{commandline})
\]

commandline

(Input) Character*(*) Command to be passed to the operating system.

Results:

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows* API CreateProcess( ) in your Fortran code.

If the function fails, call “GETLASTERRORQQ” to determine the reason. One of the following errors can be returned:

• ERR$2BIG – The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
• ERR$NOINT – The command interpreter cannot be found.
• ERR$NOEXEC – The command interpreter file has an invalid format and is not executable.
• ERR$NOMEM – Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

The command line character limit for the SYSTEMQQ function is the same limit that your operating system command interpreter accepts.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SYSTEM”

Example

USE IFPORT
LOGICAL(4) result
result = SYSTEMQQ('copy c:\bin\fmath.dat & 
    c:\dat\fmath2.dat')

TIME

Portability Function or Subroutine: The function returns the system time, in seconds, since
00:00:00 Greenwich mean time, January 1, 1970. The subroutine fills a parameter with the current
time as a string in the format hh:mm:ss.

Module: USE IFPORT

Function Syntax:
result = TIME ( )

Subroutine Syntax:
CALL TIME ( string)

string
(Output) Character*(*) . Current time, based on a 24-hour clock, in the format hh:mm:ss, where hh,
mm, and ss are two-digit representations of the current hour, minutes past the hour, and seconds
past the minute, respectively.

Results:
The result type is INTEGER(4). The result value is the number of seconds that have elapsed since
00:00:00 Greenwich mean time, January 1, 1970.
The value returned by this routine can be used as input to other portability date and time functions.

NOTE. TIME is an intrinsic procedure unless you specify USE IFPORT.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

See Also: the TIME subroutine in the Language Reference

Example
USE IFPORT
INTEGER(4) int_time
character*8 char_time
int_time = TIME( )
call TIME(char_time)
print *, 'Integer: ', int_time, 'time: ', char_time
TIMEF

Portability Function: Returns the number of seconds since the first time it is called, or zero.

Module: USE IFPORT

Syntax

result = TIMEF()

Results:
The result type is REAL(4). The result value is the number of seconds that have elapsed since the first time TIMEF was called.
The first TIMEF it is called, it returns 0.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER i, j
REAL(8) elapsed_time
elapsed_time = TIMEF()
DO i = 1, 100000
  j = j + 1
END DO
elapsed_time = TIMEF()
PRINT *, elapsed_time
END

TRACEBACKQQ

Run-Time Subroutine: Provides traceback information. Uses the Intel® Visual Fortran run-time library traceback facility to generate a stack trace showing the program call stack as it appeared at the time of the call to TRACEBACKQQ().

Module: USE IFCORE

Syntax

CALL TRACEBACKQQ([string], [user_exit_code], [status], [eptr])
string
(Optional; input) CHARACTER*(*). A message string to precede the traceback output. It is recommended that the string be no more than 80 characters (one line) since that length appears better on output. However, this limit is not a restriction and it is not enforced. The string is output exactly as specified; no formatting or interpretation is done.
If this argument is omitted, no header message string is produced.

user_exit_code
(Optional; input) INTEGER(4). An exit code. Two values are predefined:
- A value of –1 causes the run-time system to return execution to the caller after producing traceback.
- A value of zero (the default) causes the application to abort execution.
Any other specified value causes the application to abort execution and return the specified value to the operating system.

status
(Optional; input) INTEGER(4). A status value. If specified, the run-time system returns the status value to the caller indicating that the traceback process was successful. The default is not to return status.
Note that a returned status value is only an indication that the "attempt" to trace the call stack was completed successfully, not that it produced a useful result.
You can include the file iosdef.for in your program to obtain symbolic definitions for the possible return values. A return value of FOR$IOS_SUCCESS (0) indicates success.

eptr
(Optional; input) Cray pointer. It is required if calling from a user-specified exception filter. If omitted, the default in null.
To trace the stack after an exception has occurred, the runtime support needs access to the exception information supplied to the filter by the operating system.
The eptr argument is a pointer to T_EXCEPTION_POINTERS, returned by the Windows* API GetExceptionInformation( ), which is usually passed to a C try/except filter function. This argument must be null if you are not passing a valid pointer to T_EXCEPTION_POINTERS. For more information, see "Obtaining Traceback Information with TRACEBACKQQ" in Building Applications.
The TRACEBACKQQ routine provides a standard way for an application to initiate a stack trace. It can be used to report application detected errors, debugging, and so forth. It uses the stack trace support in the Intel Visual Fortran run-time library, and produces the same output that the run-time library produces for unhandled errors and exceptions.
The error message string normally included by the run-time system is replaced with the user-supplied message text, or omitted if no string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the run-time system.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also:** “GETEXCEPTIONPTRSOQ (i32, i32em)”, and "Obtaining Traceback Information with TRACEBACKQQ", "Using Traceback Information", and "Run-Time Message Display and Format" in *Building Applications*

**Examples**

The following example generates a traceback report with no leading header message, from wherever the call site is, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ()
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ("My application message string")
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution, returning a status code of 123 to the operating system:

```
USE IFCORE
CALL TRACEBACKQQ(STRING="Bad value for TEMP",USER_EXIT_CODE=123)
```

Consider the following:

```
... 
USE IFCORE
INTEGER(4) RTN_STS
INCLUDE 'IOSDEF.FOR'
...
CALL TRACEBACKQQ(USER_EXIT_CODE=-1,STATUS=RTN_STS)
IF (RTN_STS .EQ. FOR$IOS_SUCCESS) THEN
  PRINT *, 'TRACEBACK WAS SUCCESSFUL'
END IF
...
```

This example generates a traceback report with no header string, and returns to the caller to continue execution of the application. If the traceback process succeeds, a status will be returned in variable RTN_STS.
For more examples, including one showing a Cray pointer, see "Obtaining Traceback Information with TRACEBACKQQ" in *Building Applications*.

**TTYNAM**

**Portability Subroutine:** Specifies a terminal device name.

**Module:** USE IFPORT

**Syntax**

```fortran
CALL TTYNAM (string, lunit)
```

**string**

(Output) Character*(*) . Name of the terminal device. If the Fortran logical unit is not connected to a terminal, it returns a string filled with blanks.

**lunit**

(Input) INTEGER(4). A Fortran logical unit number.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**UNLINK**

**Portability Function:** Deletes the file given by path.

**Module:** USE IFPORT

**Syntax**

```fortran
result = UNLINK (name)
```

**name**

(Input) Character*(*) . Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

**Results:**

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

- ENOENT: The specified file could not be found.
- EACCES: The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “SYSTEM”. “DELDIRQQ”

Example
USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirname
READ *, dirname
ISTATUS = UNLINK (dirname)
IF (ISTATUS) then
    print *, 'Error ', ISTATUS
END IF
END

UNPACKTIMEQQ

Portability Subroutine: Unpacks a packed time and date value into its component parts.

Module: USE IFPORT

Syntax
CALL UNPACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

timedate
(Input) INTEGER(4). Packed time and date information.
iyr
(Output) INTEGER(2). Year (xxxx AD).
imon
(Output) INTEGER(2). Month (1 - 12).
iday
(Output) INTEGER(2). Day (1 - 31).
ihr
(Output) INTEGER(2). Hour (0 - 23).
imin
(Output) INTEGER(2). Minute (0 - 59).
isec
(Output) INTEGER(2). Second (0 - 59).

GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values. Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also: “PACKTIMEQQ”, “GETFILEINFOQQ”

Example
USE IFPORT
CHARACTER(80) file
TYPE (FILE$INFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec
file = 'd:\f90ps\bin\t???.*'
handle = FILE$FIRST

UNREGISTERMOUSEEVENT

QuickWin Function: Removes the callback routine registered for a specified window by an earlier call to REGISTERMOUSEEVENT. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

result = UNREGISTERMOUSEEVENT (unit, mouseevents)

unit
(Input) INTEGER(4) on IA-32 processors; INTEGER(8) on Intel Itanium and Intel EM64T processors. Unit number of the window whose callback routine on mouse events is to be unregistered.
mouseevents

(Input) INTEGER(4). One or more mouse events handled by the callback routine to be unregistered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

• MOUSE$LBUTTONDOWN – Left mouse button down
• MOUSE$LBUTTONUP – Left mouse button up
• MOUSE$LBUTTONDBLCLK – Left mouse button double-click
• MOUSE$RBUTTONDOWN – Right mouse button down
• MOUSE$RBUTTONUP – Right mouse button up
• MOUSE$RBUTTONDBLCLK – Right mouse button double-click
• MOUSE$MOVE – Mouse moved

Results:
The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

• MOUSE$BADUNIT – The unit specified is not open, or is not associated with a QuickWin window.
• MOUSE$BADEVENT – The event specified is not supported.

Once you call UNREGISTERMOUSEEVENT, QuickWin no longer calls the callback routine specified earlier for the window when mouse events occur. Calling UNREGISTERMOUSEEVENT when no callback routine is registered for the window has no effect.

Compatibility
QUICKWIN GRAPHICS LIB

See Also: "REGISTERMOUSEEVENT", "WAITONMOUSEEVENT", "Using QuickWin" in Building Applications

WAITONMOUSEEVENT

QuickWin Function: Waits for the specified mouse input from the user. This function is only available on Windows* systems.

Module: USE IFQWIN

Syntax

    result = WAITONMOUSEEVENT (mouseevents, keystate, x, y)

mouseevents

(Input) INTEGER(4). One or more mouse events that must occur before the function returns. Symbolic constants for the possible mouse events are:
• MOUSE$LBUTTONDOWN – Left mouse button down
• MOUSE$LBUTTONUP – Left mouse button up
• MOUSE$LBUTTONDBLCLK – Left mouse button double-click
• MOUSE$RBUTTONDOWN – Right mouse button down
• MOUSE$RBUTTONUP – Right mouse button up
• MOUSE$RBUTTONDBLCLK – Right mouse button double-click
• MOUSE$MOVE – Mouse moved

keystate
(Output) INTEGER(4). Bitwise inclusive OR of the state of the mouse during the event. The value returned in keystate can be any or all of the following symbolic constants:
• MOUSE$KS_LBUTTON - Left mouse button down during event
• MOUSE$KS_RBUTTON - Right mouse button down during event
• MOUSE$KS_SHIFT - SHIFT key held down during event
• MOUSE$KS_CONTROL - CTRL key held down during event

x
(Output) INTEGER(4). X position of the mouse when the event occurred.
y
(Output) INTEGER(4). Y position of the mouse when the event occurred.

Results:
The result type is INTEGER(4). The result is the symbolic constant associated with the mouse event that occurred if successful. If the function fails, it returns the constant MOUSE$BADEVENT, meaning the event specified is not supported.

WAITONMOUSEEVENT does not return until the specified mouse input is received from the user. While waiting for a mouse event to occur, the status bar changes to read "Mouse input pending in XXX", where XXX is the name of the window. When a mouse event occurs, the status bar returns to its previous value.

A mouse event must happen in the window that had focus when WAITONMOUSEEVENT was initially called. Mouse events in other windows will not end the wait. Mouse events in other windows cause callbacks to be called for the other windows, if callbacks were previously registered for those windows.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference
between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system’s CONTROL PANEL/MOUSE.

**Compatibility**

QUICKWIN GRAPHICS LIB

**See Also:** "REGISTERMOUSEEVENT", "UNREGISTERMOUSEEVENT", "Using QuickWin" in *Building Applications*

**Example**

```fortran
USE IFQWIN
INTEGER(4) mouseevent, keystate, x, y, result
...
mouseevent = MOUSE$RBUTTONDOWN .OR. MOUSE$LBUTTONDOWN
result = WAITONMOUSEEVENT (mouseevent, keystate, x, y)
!
! Wait until right or left mouse button clicked, then check the keystate
! with the following:
!
if ((MOUSE$KS_SHIFT .AND. keystate) == MOUSE$KS_SHIFT) then &
   & write (*,*) 'Shift key was down'
if ((MOUSE$KS_CONTROL .AND. keystate) == MOUSE$KS_CONTROL) then &
   & write (*,*) 'Ctrl key was down'
```

**WRAPON**

**Graphics Function:** Controls whether text output is wrapped. This function is only available on Windows® systems.

**Module:** USE IFQWIN

**Syntax**

```fortran
result = WRAPON (option)
```

**option**

(Input) INTEGER(2). Wrap mode. One of the following symbolic constants:

- $GWRAPOFF – Truncates lines at right edge of window border.
- $GWRAPON – Wraps lines at window border, scrolling if necessary.

**Results:**

The result type is INTEGER(2). The result is the previous value of *option*. 
WRAPON controls whether text output with the OUTTEXT function wraps to a new line or is truncated when the text output reaches the edge of the defined text window. WRAPON does not affect font routines such as OUTGTEXT.

example of, 2-54, 2-56, 2-68

DLGINITWITHRESOURCEHANDLE (W*32, W*64), 2-54
when to use, 2-54

DLGISDLGMESSAGE (W*32, W*64), 2-55, 2-59
example of, 2-51, 2-56
when to use DLGISDLGMESSAGEWITHDLG, 2-55

DLGISDLGMESSAGEWITHDLG (W*32, W*64), 2-55
when to use, 2-55

DLGMODAL (W*32, W*64), 2-51, 2-56, 2-61
default return value for, 2-57
example of, 2-58, 2-68
rules for determining parent window, 2-57
subroutine setting return value of, 2-65
when to use DLG MODALWITHPARENT, 2-57

DLG MODALWITHPARENT (W*32, W*64), 2-56
to use, 2-57

DLG MODELESS (W*32, W*64), 2-51, 2-55, 2-58, 2-61
attribute of variable in, 2-58
constants indicating display for dialog box, 2-58
example of, 2-56, 2-60
rules for determining parent window, 2-59

DLGSENDCTRLMESSAGE (W*32, W*64), 2-61
element of, 2-61
function to call before using, 2-61

DLGSET (W*32, W*64), 2-51, 2-62
element of, 2-63

DLGSETCHAR (W*32, W*64), 2-62

DLGSETCTRLMESSAGEHANDLER (W*32, W*64), 2-64
element of, 2-65
function returning IDispatch pointer, 2-65

DLGSETINT (W*32, W*64), 2-62

DLGSETLOG (W*32, W*64), 2-62

DLGSETRETURN (W*32, W*64), 2-57, 2-65
element of, 2-66

DLGSETSUB (W*32, W*64), 2-57, 2-65
example of, 2-66

DLGUNINIT (W*32, W*64), 2-70
example of, 2-56, 2-70

DMOD
See your language reference

DOUBLE PRECISION
functions converting to, 2-48, 2-164

DRAND, 2-71
example of, 2-71

DRANDM, 2-71

DRANSET, 2-72

Drive
function returning available space on, 2-113
function returning path of, 2-112
function returning total size of, 2-113
function specifying current as default, 2-24
Drive control or inquiry
portability routines for, 1-5
Drives
function returning available, 2-115
DSHIFTL
See your language reference
DSHIFTR
See your language reference
DTIME, 2-72
example of, 2-73
E
Elapsed time
function causing a subroutine to run after, 2-5
function converting, 2-42
function returning, 2-45, 2-72, 2-75
Electromagnetic wave theory
functions used in, 2-19, 2-44
ELLIPSE (W*32, W*64), 2-73
constants indicating fill for, 2-73
example of, 2-74, 2-129, 2-389
ELLIPSE_W (W*32, W*64), 2-73
constants indicating fill for, 2-73
Ellipses
functions drawing, 2-73
Elliptical arcs
drawing, 2-8
Environment
function cleaning up run-time, 2-86
function initializing run-time, 2-87
Environment variables
function finding file in path specified by, 2-77
function returning value of, 2-116
function scanning for, 2-382
function setting value of, 2-397
subroutine returning value of, 2-115
Errno names, 2-170
Error

subroutine sending last detected to standard error stream, 2-245
Error codes, 2-170
Error handling
portability routines for, 1-5
run-time routines for, 1-26
Error numbers, 2-170
Errors
functions returning most recent run-time, 2-130,
2-131
subroutine returning message for last detected, 2-96
ETIME, 2-75
example of, 2-75
Exception flags
function returning settings of floating-point, 2-86
function setting floating-point, 2-87
subroutine clearing in status word, 2-29
Execution
subroutine delaying for a program, 2-446
subroutine suspending for a process, 2-445
EXIT
See your language reference
Exit behavior
constants indicating (W*32, W*64), 2-119
function returning QuickWin, 2-119
function setting QuickWin, 2-399
Exit parameters
function setting QuickWin, 2-399
External unit 5
function returning next character from, 2-101
External unit 6
function writing a character to, 2-258
External unit buffer
subroutine flushing, 2-81
F
FDATE, 2-76
example of, 2-76
FGETC, 2-77
example of, 2-77
POSIX version of, 2-287
Field component
   POSIX subroutine returning array values stored in, 2-263
   POSIX subroutine returning value stored in, 2-261
   POSIX subroutine returning values stored in array element, 2-278
   POSIX subroutine setting array element, 2-280
   POSIX subroutine setting value of, 2-262
   POSIX subroutine setting value of array, 2-264

Figure characteristics
   graphics routines for (W*32, W*64), 1-19

File access mode
   function setting, 2-401

File descriptor
   POSIX subroutine defining an action for (L*X, M*X32), 2-274
   POSIX subroutine duplicating, 2-278

File directory control or inquiry
   portability routines for, 1-5

File management
   portability routines for, 1-6
   run-time routines for, 1-25

File path
   function splitting into components, 2-448

File position
   functions returning, 2-94, 2-141

Files
   function changing access mode of, 2-26
   function deleting, 2-47
   function finding specified, 2-77
   function performing flush of, 2-38
   function renaming, 2-375, 2-376
   function repositioning, 2-90
   function returning full path of, 2-95
   function returning information about, 2-91, 2-120, 2-197, 2-475
   function returning next available character from, 2-77
   function setting modification time for, 2-402
   function testing access mode of, 2-3
   function using path to delete, 2-484
   function writing character to, 2-89
   functions returning current position of, 2-94, 2-141
   POSIX function testing for block special, 2-306
   POSIX function testing for character, 2-307
   POSIX function testing for directory, 2-308
   POSIX function testing for regular, 2-309
   POSIX function testing for special FIFO, 2-308
   POSIX subroutine changing access mode of, 2-271
   POSIX subroutine changing the owner and group of, 2-272
   POSIX subroutine closing, 2-273
   POSIX subroutine creating a FIFO, 2-313
   POSIX subroutine creating a link to, 2-310
   POSIX subroutine creating new or rewriting, 2-277
   POSIX subroutine determining accessibility of, 2-266
   POSIX subroutine flushing, 2-286
   POSIX subroutine opening, 2-314
   POSIX subroutine positioning, 2-311
   POSIX subroutine reading from, 2-321
   POSIX subroutine returning configuration value, 2-290, 2-317
   POSIX subroutine setting access times for, 2-355
   POSIX subroutine writing to, 2-361

Fill mask
   function filling an area using, 2-78, 2-80
   subroutine setting to new pattern, 2-403

Fill shapes
   subroutine returning pattern used to, 2-123

FINDFILEQQ, 2-77
   example of, 2-78

Floating-point control word
   subroutine returning, 2-383
   subroutine setting, 2-190, 2-393

Floating-point exception flags
   function returning settings of, 2-86
   function setting, 2-87

Floating-point inquiry and control
   portability routines for, 1-6
   run-time routine for, 1-26

Floating-point status word
   subroutine clearing exception flags in, 2-29
   subroutines returning, 2-141, 2-474
   FLOODFILL (W*32, W*64), 2-78
   example of, 2-79
   FLOODFILL_W (W*32, W*64), 2-78
   FLOODFILLRGB (W*32, W*64), 2-80
   example of, 2-81
   FLOODFILLRGB_W (W*32, W*64), 2-80
   FLUSH, 2-81
Focus
  function determining which window has, 2-176
  function setting, 2-82
FOCUSQQ (W*32, W*64), 2-82
  related to SETACTIVEQQ, 2-82
Font characteristics
  function returning, 2-125
Font-based characters
  routines displaying (W*32, W*64), 1-21
Font-related library functions, 2-125, 2-127, 2-174, 2-237, 2-406
  effect of, 2-175
Fonts
  function initializing, 2-174
  function returning characteristics of, 2-125
  function returning orientation of text for, 2-127
  function returning size of text for, 2-127
  function setting for OUTGTEXT, 2-406
  function setting orientation angle for text, 2-409
FOR_DESCRIPTOR_ASSIGN (W*32, W*64), 2-83
  example of, 2-84
FOR_GET_FPE, 2-86
  example of, 2-86
  for_rtl_finish_, 2-86
  example of, 2-87
  for_rtl_init_, 2-87
  example of, 2-87
FOR_SET_FPE, 2-87
  example of, 2-88
FOR_SET_REENTRANCY, 2-88
  example of, 2-89
  modes for, 2-88
Formatting
  NLS routines for (W*32, W*64), 1-8
FPUTC, 2-89
  example of, 2-90
  POSIX version of, 2-291
SEEK, 2-90
  example of, 2-91
  file positions for, 2-91
  POSIX version of, 2-292
FSSTAT, 2-91
  constants defining Windows access modes in, 2-93

G
GERROR, 2-96
  example of, 2-97
GETACTIVEQQ (W*32, W*64), 2-97
GETARG
  See your language reference
GETCOLOR (W*32, W*64), 2-99
  example of, 2-100
GETCOLORRGB (W*32, W*64), 2-100
  example of, 2-101
GETC, 2-101
  example of, 2-102
  POSIX version of, 2-295
GETCHARQQ, 2-102
  and PASSDIRKEYSQQ, 2-103
  and PEEKCHARQQ, 2-103
  example of, 2-103
GETCOLOR (W*32, W*64), 2-104
  and FLOODFILL, 2-79
  example of, 2-104
GETCOLORRGB (W*32, W*64), 2-105
  and FLOODFILLRGB, 2-80
  example of, 2-81, 2-106
GETCONTROLFPQQ, 2-107
  constants defining control word, 2-107
  example of, 2-108
GETCURRENTPOSITION (W*32, W*64), 2-109
  example of, 2-110
GETCURRENTPOSITION, 2-110
GETCWD, 2-110
  example of, 2-110
  POSIX version of, 2-296
GETDAT, 2-111
  example of, 2-111
GETDRIVEDIRQQ, 2-112
  example of, 2-113
GETDRIVESIZEQQ, 2-113
  example of, 2-114
GETDRIVESQQ, 2-115
  example of, 2-114
GETENV, 2-115
  example of, 2-116
  POSIX version of, 2-297
GETENVQQ, 2-116
  example of, 2-117
GETEXCEPTIONPTRSQQ (W*32, W*64), 2-118
  example of, 2-118
GETEXITQQ (W*32, W*64), 2-119
  example of, 2-119
GETFILEINFOQQ, 2-120
  constants indicating handle for, 2-121
  example of, 2-122
GETFILLMASK (W*32, W*64), 2-123
  example of, 2-124
GETFONTINFO (W*32, W*64), 2-125
  example of, 2-126
GETGID, 2-126
  example of, 2-126
  POSIX version of, 2-298
GETGTEXTENT (W*32, W*64), 2-127
  example of, 2-127
GETGTEXTROTATION (W*32, W*64), 2-127
  example of, 2-128
GETHwndQQ (W*32, W*64), 2-128
GETIMAGE (W*32, W*64), 2-129
  example of, 2-129
  function returning memory needed for, 2-172
GETIMAGE_W (W*32, W*64), 2-129
GETLASTERROR, 2-130
GETLASTERRORQQ, 2-131
GETLINESTYLE (W*32, W*64), 2-132
  example of, 2-133
GETLOG, 2-133
  example of, 2-133
  POSIX version of, 2-302
GETPHYSCOORD (W*32, W*64), 2-134
  example of, 2-134
GETPID, 2-135
  example of, 2-135
  POSIX version of, 2-303
GETPIXEL (W*32, W*64), 2-135
GETPIXEL_W (W*32, W*64), 2-135
GETPIXELRGB (W*32, W*64), 2-136
  example of, 2-137
GETPIXELRGB_W (W*32, W*64), 2-136
GETPIXELS (W*32, W*64), 2-138
GETPIXELSRGB (W*32, W*64), 2-139

GETTEXTCOLOR (W*32, W*64), 2-144
GETTEXTCOLORRGB (W*32, W*64), 2-145
  example of, 2-146
GETTEXTPOSITION (W*32, W*64), 2-147
  example of, 2-147
GETTEXTWINDOW (W*32, W*64), 2-148, 2-154
  example of, 2-134, 2-148
GETTIM, 2-149
  example of, 2-111
GETTIMEOFDAY, 2-149
GETUID, 2-150
  example of, 2-150
  POSIX version of, 2-306
GETUNITQQ (W*32, W*64), 2-150
GETVIEWCOORD (W*32, W*64), 2-151
  example of, 2-134
GETVIEWCOORD_W (W*32, W*64), 2-151
GETWINDOWCONFIG (W*32, W*64), 2-152
  and SETWINDOWCONFIG, 2-153
  example of, 2-154
GETWRITEMODE (W*32, W*64), 2-155
  example of, 2-156
values for write mode, 2-155
GETWSIZEQQ (W*32, W*64), 2-156
GMTIME, 2-157
example of, 2-158
Graphics
routines to draw (W*32, W*64), 1-19
Graphics output
function returning background color index for, 2-99
function returning background RGB color for, 2-100
function setting background color index for, 2-386
function setting background RGB color for, 2-388
subroutine limiting to part of screen, 2-389
Graphics position
routines changing, 2-109
subroutine moving to a specified point, 2-219
subroutine returning coordinates for current, 2-109
Graphics routines (W*32, W*64), 1-16
ARC and ARC_W, 2-8
CLEARSCREEN, 2-28
converting and setting coordinates, 1-19

Memory assignment
   run-time routine for, 1-26

Menu command
   function simulating selection of, 2-30

Menu items
   definition order of, 2-179
   function changing callback routine of, 2-216
   function changing text string of, 2-218
   function deleting from QuickWin, 2-47
   function modifying the state of, 2-215
   function to insert, 2-177

Menu state
   constants indicating, 2-6, 2-177, 2-215

Menus
   definition order of, 2-179
   function appending child window list to, 2-435
   function appending item to, 2-6
   function inserting item in, 2-177
   function setting top-level for append list, 2-435

Message box
   constants determining objects and properties of, 2-214
   function displaying, 2-213
   function specifying text for, 2-3

MESSAGEBOXQQ (W*32, W*64), 2-213
   example of, 2-215

MODIFYMENUFLAGSQQ (W*32, W*64), 2-215
   example of, 2-216

MODIFYMENUROUTINEQQ (W*32, W*64), 2-216
   predefined routines for, 2-217

MODIFYMENUSSTRINGQQ (W*32, W*64), 2-218
   example of, 2-219
Index

Mouse cursor
  function setting the shape of, 2-413

Mouse events
  constants defining, 2-370
  function registering callback routine for, 2-370
  function unregistering callback routine for, 2-486
  function waiting for, 2-487

Mouse input
  function waiting for, 2-487

MOVETO (W*32, W*64), 2-219
  example of, 2-110, 2-140, 2-220, 2-237, 2-393

MOVETO_W (W*32, W*64), 2-219

Multibyte characters
  function equivalent to INCHARQQ, 2-204
  function equivalent to INDEX, 2-205
  function equivalent to SCAN, 2-211
  function equivalent to VERIFY, 2-213
  function performing context-sensitive test for, 2-212
  function returning first, 2-206
  function returning length for codepage, 2-204
  function returning number and character, 2-204
  functions comparing strings of, 2-208

Multibyte-character string
  function converting to Unicode, 2-201
  function returning length (including blanks), 2-207
  function returning length (no blanks), 2-208
  function returning length of first character in, 2-201
  function returning position of next character in, 2-210
  function returning position of previous character in, 2-211

Multibyte-charset string
  function equivalent to INCHARQQ, 2-204
  function equivalent to INDEX, 2-205
  function equivalent to SCAN, 2-211
  function equivalent to VERIFY, 2-213
  function performing context-sensitive test for, 2-212
  function returning first, 2-206
  function returning length for codepage, 2-204
  function returning number and character, 2-204
  functions comparing strings of, 2-208

example of, 2-239, 2-383

P

PACKTIMEQQ, 2-239  
example of, 2-240
Page keys  
function determining behavior of, 2-240
PASSDIRKEYSQQ (W*32, W*64), 2-240  
and GETCHARQQ, 2-103  
constants defining actions for, 2-240  
example of, 2-241, 2-242
Password information  
POSIX subroutine returning (L*X, M*X32), 2-304
Path  
constant allocating the largest possible length for, 2-95  
function returning working directory, 2-112  
function splitting into components, 2-448
Pathname  
POSIX subroutine generating a terminal (L*X, M*X32), 2-277
Pattern used to fill shapes  
subroutine returning, 2-123
PEEKCHARQQ, 2-244  
and GETCHARQQ, 2-103  
example of, 2-244
PERERROR, 2-245  
example of, 2-245
Physical coordinates  
subroutine converting from viewport coordinates, 2-134  
subroutine converting to viewport coordinates, 2-151
PIE (W*32, W*64), 2-245  
example of, 2-247
Pie graphic  
function testing for endpoints of, 2-98
PIE_W (W*32, W*64), 2-245
Pie-shaped wedge
  function to draw, 2-245

Pixel
  function returning color index for, 2-135
  function returning RGB color value for, 2-136
  function setting color index for, 2-415
  function setting RGB color value for, 2-416

Pixels
  function returning color index for multiple, 2-138
  function returning RGB color value for multiple, 2-139
  function setting color index for multiple, 2-418
  function setting RGB color value for multiple, 2-419

TTYNAM, 2-484
POSIX version of, 2-353

V
Variant type
constants indicating, 2-11, 2-14, 2-16
Viewport
subroutine using to redefine graphics, 2-429
Viewport area
subroutine erasing and filling, 2-28
Viewport coordinates
function determining endpoints of arc or pie, 2-98
function returning color index of pixel, 2-135
function returning RGB color of pixel, 2-136
function using to draw a line, 2-191
function using to draw a line between arrays, 2-192,
2-193
function using to draw a line within an array, 2-256
function using to draw Bezier curves, 2-248, 2-252
function using to draw circle or ellipse, 2-73
function using to draw elliptical arcs, 2-8
function using to draw polygons, 2-254
function using to draw rectangles, 2-368
function using to draw wedge, 2-245
function using to read from bitmap file, 2-196
function using to return storage size of image, 2-172
function using to save images to bitmap file, 2-381
function using to set pixel to color index, 2-415
function using to set pixel to RGB value, 2-416
function using to transfer an image, 2-258
functions filling (color index), 2-78
functions filling (RGB), 2-80
subroutine converting to physical coordinates, 2-134
subroutine converting to windows coordinates, 2-154
subroutine returning current graphics, 2-109
subroutine storing image in rectangle, 2-129
subroutine using to move graphics, 2-219
subroutines converting from physical coordinates,
2-151
Viewport origin
subroutine moving, 2-429
Viewport-coordinate origin
subroutine moving, 2-429
subroutine setting, 2-429

U
Unit 5
function returning next character from, 2-101
Unit 6
function writing a character to, 2-258
Unit number
function testing whether it’s a terminal, 2-186

Windows* bitmap file
- function saving an image into, 2-381

Windows* coordinates
- function returning color index of pixel, 2-135
- function returning RGB color of pixel, 2-136
- function using to define a window, 2-430
- function using to set pixel to color index, 2-145
- function using to set pixel to RGB value, 2-219
- function using to transfer an image, 2-258
- functions filling (color index), 2-78
- functions filling (RGB), 2-80
- subroutine converting from viewport coordinates, 2-154
- subroutine returning current graphics, 2-109
- subroutine storing image in rectangle, 2-219
- subroutines converting from physical coordinates, 2-219

Windows* properties
- function returning, 2-152
- function setting, 2-431, 2-438

WINEXIT predefined QuickWin routine, 2-6
WINFULLSCREEN predefined QuickWin routine, 2-6
WININDEX predefined QuickWin routine, 2-6
